

1 **Organize, Then Vote: Exploring Cognitive Load in Quadratic Survey Interfaces**

2
3 ANONYMOUS AUTHOR(S)*

4
5 Quadratic Surveys (QS) elicit more accurate individual preferences than traditional surveys, such as Likert-scale surveys. However, the
6 cognitive load associated with QS has hindered its adoption in digital surveys for collective decision-making. We introduce a two-phase
7 “organize-then-vote” QS interface based on decision-making and preference construction theories designed to lessen the cognitive load.
8 Since interface design significantly impacts survey results and accuracy, our design scaffolds survey takers’ decision-making while
9 managing the cognitive load imposed by QS. In a 2x2 between-subject in-lab study on public resource allotment, we compared our
10 interface with a traditional text interface across QS with 6 (short) and 24 (long) options. Our interface reduced satisficing behaviors
11 arising from cognitive overload in long QS conditions. Participants using our interface in the long QSs shifted their cognitive effort
12 from mechanical operations to constructing more comprehensive preferences. This research clarifies how human-centered design
13 improves preference elicitation tools for collective decision-making.

26
27 **1 Introduction**

28
29 Designing intuitive survey interfaces is crucial for accurately capturing respondents’ preferences, which directly impact
30 the quality and reliability of the data collected. Recent Human-Computer Interaction (HCI) studies highlight how
31 certain survey response formats can increase errors [1, 2] and influence survey effectiveness [3]. In this paper, our
32 goal is to introduce an effective interface for **Quadratic Surveys (QS)**, a survey tool designed to elicit preferences
33 more accurately than traditional methods [4]. Despite the promise of QS, there has been no research on designing
34 interfaces to support its unique quadratic mechanisms [5], where participants must rank and rate items — a task that
35 poses significant cognitive challenges. To popularize QS and ensure high-quality data, this paper addresses the question:
36 *How can we design interfaces to support participants in completing Quadratic Surveys (QS) more effectively?*

37
38 We envision an effective interface that navigates participants through the complex mechanism and preference
39 construction process, tailored to the unique challenges of QS. QS improves accuracy in individual preference elicitation
40 compared to traditional methods like Likert scales by requiring participants to make trade-offs using a fixed budget
41 of credits, where purchasing k votes for an option in QS costs k^2 credits [6, 4]. This quadratic cost structure forces
42 respondents to carefully evaluate their preferences, balancing the strength of their support or opposition against the

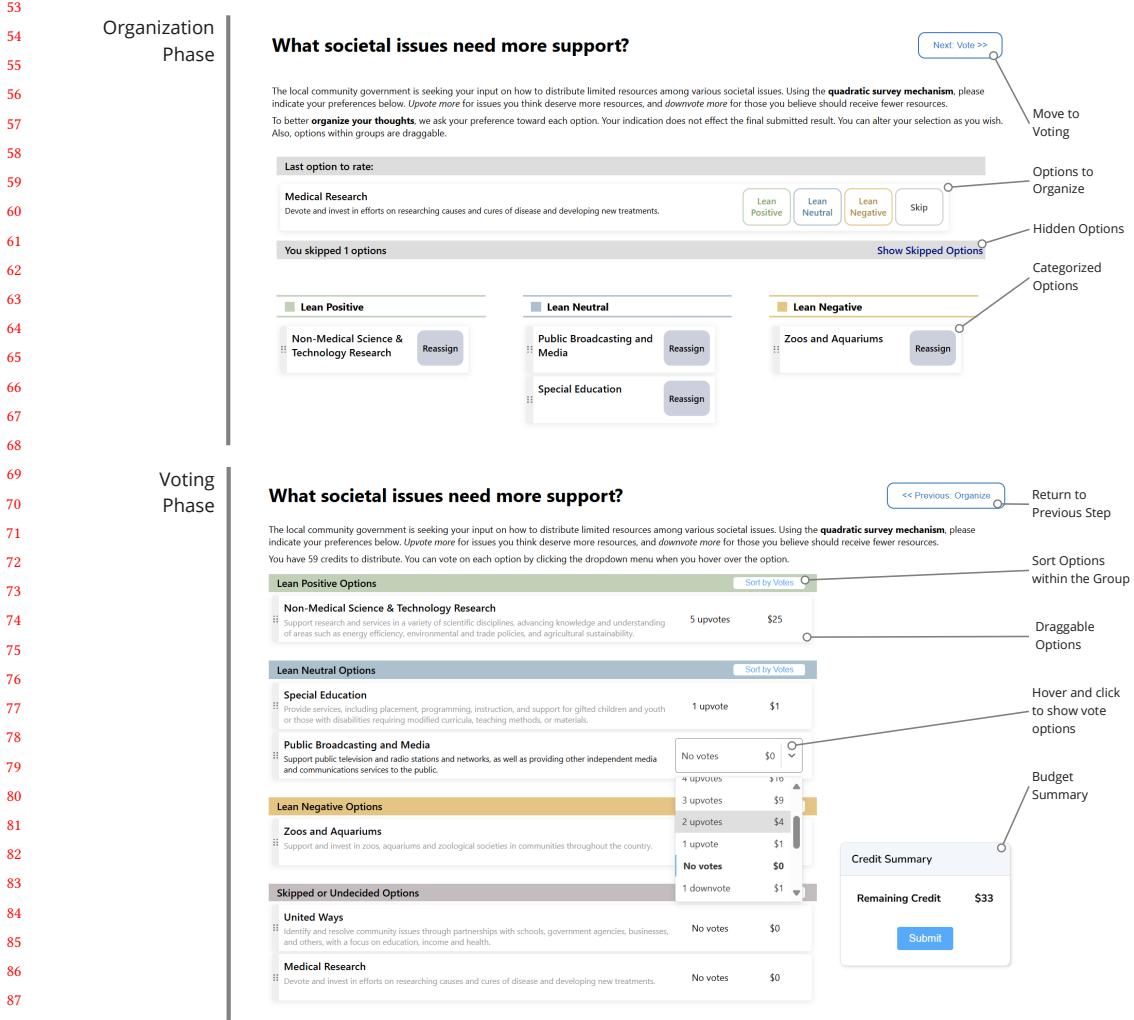

Fig. 1. The Two-Phase Interface: The interface consists of two phases. Survey respondents can navigate between phases using the top right button. In the organization phase, the interface presented one option at a time to the respondents, and they chose four choices: “Lean Positive”, “Lean Neutral”, “Lean Negative”, or “Skip”. Skipped options are hidden and can be evaluated later. The chosen options will be listed below. Items can be dragged and dropped across categories or returned to the stack. In the voting phase, options are listed in the order of the four categories. When hovering over each option, respondents can select a vote for that option using the dropdown. Each dropdown contains the cost associated with the vote. A sort button allows ascending sorting within each category. A summary box tracks the remaining credit balance.

limited budget. While this cost structure forces them to make thoughtful trade-offs, this complexity also increases cognitive load, making it mentally taxing to weigh costs, evaluate options, and construct rankings [7]. Moreover, QS, often referred to as Quadratic Voting (QV) in voting scenarios, can involve hundreds of options [8, 9], increasing the risk of cognitive overload and satisficing [10, 11, 12]. We propose that an effective interface tailored to support users through these complex trade-offs can reduce cognitive load and facilitate better preference construction.

Manuscript submitted to ACM

To date, existing quadratic mechanism-powered applications simply present options, allow vote adjustments and automatically calculate votes, costs, and budget usage. These designs focused heavily on the mechanics operating the tool, rather than supporting possible challenges these application users faced. Survey interface literature, while addressing decision-making and usability, most focus on traditional surveys that do not share the unique option-to-option trade-offs that QS introduces [13, 14, 15, 16, 17, 1]. More specifically, managing cognitive load [18, 19, 16, 20, 21] and scaffolding challenging tasks [22, 23, 24, 25] like preference construction, are opportunities where user interfaces have shown their promises. As a result, it remains unclear how different interface designs might support QS in reducing cognitive load and aiding preference construction.

After multiple design iterations, we propose a novel interactive two-phase “organize-then-vote” QS interface (referred to two-phase interface for short, Figure 1) that integrates three key elements. First, the interface scaffolds the preference construction process by having participants initially categorize the survey options into “Lean Positive,” “Lean Neutral,” or “Lean Negative.” This serves as a cognitive warm-up, easing participants into the more complex QS voting task. Second, the interface arranges the options according to these categorizations, providing a structured visual layout. Third, participants can refine the positions of these options using drag-and-drop functionality, giving them greater control and agency in the preference-construction process. These design features are aligned with preference construction theory and build upon prior research in interface design to reduce cognitive load and enhance user engagement.

To explore how these interface elements mitigate the cognitive load and support preference construction in Quadratic Surveys, we pose the following research questions:

- RQ1. How does the number of options in Quadratic Surveys impact respondents’ cognitive load?
- RQ2a. How does the two-phase interface impact respondents’ cognitive load compared to a single-phase text interface?
- RQ2b. What are the similarities and differences in sources of cognitive load across the two interfaces?
- RQ3. What are the differences in Quadratic Survey respondents’ behaviors when coping with long lists of options across the two-phase interface and the single-phase text interface?

We invited 41 participants to a lab study comparing our two-phase interface with a baseline to understand how different interface designs and option lengths (6 options or 24 options) impact cognitive load. Qualitative findings, measured using the NASA Task Load Index (NASA-TLX) and semi-structured interviews, revealed that participants using the two-phase interface experienced cognitive demand more from strategic, holistic thinking compared to personal relevance and operational tasks, particularly in longer surveys. Quantitative results showed that, although participants spent more time per option, they made faster decisions during the voting phase, suggesting a more efficient distribution of cognitive effort. We concluded that the two-phase interface mitigated cognitive overload in long QS surveys and shifted mental load toward more strategic thinking, reducing reliance on mental shortcuts like satisficing [10].

Contributions. We contribute to the HCI community by proposing the first interface specifically designed for QS and QV-like applications, aimed at reducing cognitive challenges and scaffolding preference construction through a two-phase interface with direct manipulation. Before our work, no research had explored QS interfaces, particularly for long surveys prone to cognitive overload. Few studies in HCI address interfaces for surveys and questionnaires. Our study demonstrated how user interfaces can facilitate preference construction *in situ* and reduce satisficing behaviors by promoting incremental updates and deeper engagement with survey items through interface elements. Additionally, our interview is also the first in-depth qualitative analysis of user experiences with Quadratic Mechanism applications, identifying key factors contributing to cognitive load. The impact of our contribution extends beyond QS, offering

design implications for other preference-elicitation tools in complex scenarios. By making QS easier to use and more accurate, our design also encourages wider adoption among researchers and practitioners. Finally, our work lays the groundwork for future studies on qualitative insights and future interface designs of quadratic mechanisms, supporting decision-makers in eliciting accurate respondents' preferences.

2 Related Work

This research lies at the intersection of three core areas: quadratic surveys, survey and voting interface design, and choice overload along with cognitive challenges. In this section, we review the related works in each of these areas.

2.1 Quadratic Survey and the Quadratic Mechanism

We introduce the term **Quadratic Survey (QS)** to describe surveys that utilize the quadratic mechanism to collect individual attitudes. The **quadratic mechanism** is a theoretical framework designed to encourage the truthful revelation of individual preferences through a quadratic cost function [5]. This framework gained popularity through **Quadratic Voting (QV)**, also known as plural voting, which uses a quadratic cost function in a voting framework to facilitate collective decision-making [26].

To illustrate how QS works, we formally define the mechanism: each survey respondent is allocated a fixed budget, denoted by B , to distribute among various options. Participants can cast n votes for or against option k . The cost c_k for each option k is derived as:

$$c_k = n_k^2 \quad \text{where} \quad n_k \in \mathbb{Z}$$

The total cost of all votes must not exceed the participant's budget:

$$\sum_k c_k \leq B$$

Survey results are determined by summing the total votes for each option:

$$\text{Total Votes for Option } k = \sum_{i=1}^S n_{i,k}$$

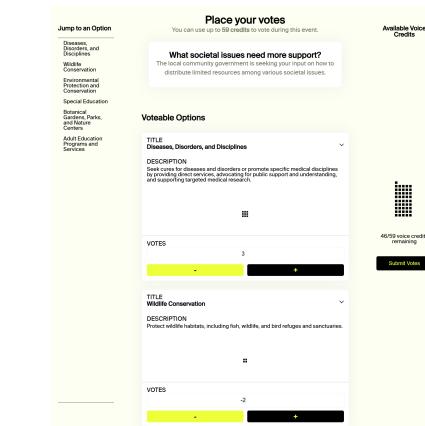

where S represents the total number of participants, and $n_{i,k}$ is the number of votes cast by participant i for option k . Each additional vote for each option increases the marginal cost linearly, encouraging participants to vote proportionally to their level of concern for an issue [27].

QS adapts these strengths of the quadratic mechanism in *voting* to encourage truthful expression of preferences in *surveys*. Unlike traditional surveys that elicit either rankings *or* ratings, QS allows for *both*, enabling participants to cast multiple votes for or against options, incurring a quadratic cost. Cheng et al. [4] showed that this mechanism aligns individual preferences with behaviors more accurately than Likert Scale surveys, particularly in resource-constrained scenarios like prioritizing user feedback on user experiences.

In recent years, empirical studies on QV have expanded into various domains [28, 29]. Applications based on the quadratic mechanism have also grown, including Quadratic Funding, which redistributes funds based on outcomes from consensus made using the quadratic mechanism [30, 31]. Recent work by South et al. [32] applies the quadratic mechanism to networked authority management, later used in Gov4git [33]. Despite the increasing breadth and depth of applications utilizing the quadratic mechanism, little attention has been paid to user experience and interface design,

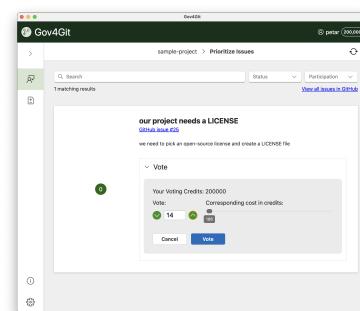

(a) Software by WeDesign, used in the first empirical QV research [6]. Little information is available about the software, except for an image from Posner and Weyl [27]. In the image, each prompt has thumbs up and down icons to update the vote in the center. The remaining budget appears as a progress bar at the top.

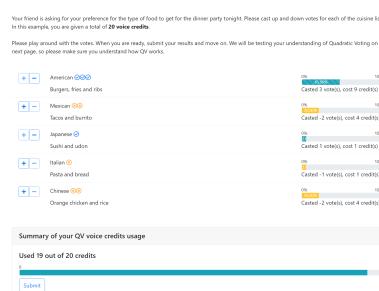

(b) An open-sourced QV interface [34] forked from GitCoin [35], used by the RadicalxChange community [36]. This interface presents total credits as small blocks. Votes are updated using plus and minus buttons, with numerical counts shown under each option and surface area as costs.

(c) An open-source QV interface [37] offers a publicly available service. Options show only the current number of votes, with credits displayed in the top right corner. This interface does not show the costs of votes but supports sorting options.

(d) The interface designed for gov4git [33] updates votes using arrows under each option, with the associated cost shown as a percentage bar to the right. A search bar exists for searching specific pull requests or issues.

(e) The interface used in the research by Cheng et al. [4] employs the most visual components. Icons depict the current number of votes, with progress bars signifying the current spending.

Fig. 2. Recent interface for applications using the quadratic mechanism.

Manuscript submitted to ACM

261 which support individuals in expressing their preference intensity. Our work aims to address this by designing interfaces
 262 supporting quadratic mechanisms.
 263

264 2.2 Design Implications from Surveys and Voting Interfaces

265 We began by examining existing QV applications (Fig. 2), which share the same mechanism as QS, and identifying
 266 shared interface components. All QV interfaces generally include:
 267

- 268 • Option list: A list of options for voting.
- 269 • Vote controls: Buttons to increase or decrease votes for each option.
- 270 • Individual vote tally: A display of the votes cast per option.
- 271 • Summary: An auto-generated summary of costs and the remaining budget.

272 These components present options, calculate costs, and allow vote adjustments. However, these interfaces focus
 273 purely on mechanics without little understanding of voter's usability needs or offering cognitive support to help
 274 them complete the task effectively. In addition, the HCI community conducted few research [38, 39] on survey and
 275 questionnaire interfaces components, with more work focusing more on alternative input modalities like bots, voice,
 276 and virtual reality [40, 41, 2, 42]. Thus, we turn to marketing and research literature for insights into how digital survey
 277 interface elements can impact user behavior and usability.

278 Research in the marketing and research communities focusing on survey and questionnaire design, usability, and
 279 interactions examines the influence of presentation styles and 'response format.' Weijters et al. [43] demonstrated that
 280 horizontal distances between options are more influential than vertical distances, with the latter recommended for
 281 reduced bias. Slider bars, which operate on a drag-and-drop principle, show lower mean scores and higher nonresponse
 282 rates compared to buttons, indicating they are more prone to bias and difficult to use. In contrast, visual analog scales
 283 that operate on a point-and-click principle perform better [44]. These studies show how even small design changes can
 284 have a large impact on usability, highlighting the importance of designing interfaces that prioritize human-centered
 285 interaction rather than focusing solely on functionality.

286 Voting interfaces are a specialized type of survey interface that not only elicit individual choices but often have
 287 consequential impacts. For example, the butterfly ballot, an atypical design, may have influenced the outcome of the
 288 2000 U.S. Presidential Election [45]. Research has shown that ballot interfaces can significantly influence democratic
 289 processes [13, 46, 47]. Several studies also highlighted how voting interface designs shift voter decisions [13], reduce
 290 usability errors [48, 49], or improve interaction [50, 51, 52, 53, 54]. We provide more details to these voting interfaces in
 291 the Appendix A.

292 From the QV implementations, response format literature, and voting interfaces, we identified how interfaces
 293 significantly influence respondent behavior, decision accuracy, and cognitive load. While these systems are functional,
 294 they lack the human-centered design needed to reduce cognitive load and make them truly usable, rather than simply
 295 operable. These burdens are especially problematic for complex systems like QS, where high cognitive demands may
 296 deter researchers and users alike. Developing effective, human-centered interfaces for QS could enhance usability,
 297 reduce cognitive overload, and increase adoption in both research and practical applications.

298 2.3 Cognitive Challenges and Choice Overload

299 The challenge of respondents making difficult decisions using quadratic mechanisms remains unexplored in the
 300 literature. Lichtenstein and Slovic [7] identified three key elements that make decisions difficult. These elements include
 301
 302 Manuscript submitted to ACM

313 making decisions in unfamiliar contexts, being forced to make trade-offs due to conflicting choices, and quantifying
 314 the value of one's opinions. QS fits all three elements: participants may encounter unfamiliar options set by the
 315 decision-maker, are constrained by budgets that require trade-offs, and cast final votes as numerical values. Thus, we
 316 believe QS introduces high cognitive load.
 317

318 According to cognitive load theory, cognitive load refers to the demands placed on a user's working memory during
 319 the interaction process, which significantly influences the usability of the system [55, 56]. Cognitive overload can
 320 adversely affect performance [57], leading individuals to rely on heuristics rather than deliberate, logical decision-
 321 making [58]. When presented with excessive information, such as too many options, individuals 'satisfice', settling
 322 for a 'good enough' solution rather than an optimal one [10, 11, 12]. Subsequently, too many options can overwhelm
 323 individuals, resulting in decision paralysis, demotivation, and dissatisfaction [59].
 324

325 Additionally, Alwin and Krosnick [60] highlighted that the use of ranking techniques in surveys can be time-
 326 consuming and potentially more costly to administer. These challenges are compounded when ranking numerous items,
 327 requiring substantial cognitive sophistication and concentration from survey respondents [61].
 328

329 Notable applications of Quadratic Voting include the 2019 Colorado House, which considered 107 bills [62], and
 330 the 2019 Taiwan Presidential Hackathon, which featured 136 proposals [63]; both used a single QV question with
 331 hundreds of options. Psychological and behavioral research highlights the importance of understanding how individuals
 332 navigate and benefit from new interfaces under long-list QS conditions. These empirical applications of QV suggest
 333 QS's potential to elicit individual preferences, emphasizing the need to study cognitive load and interface design.
 334

336 3 Quadratic Survey Interface Design

337 In this section, we present the QS interface. Using components from existing QV interfaces (Fig 2) and insights from
 338 prior literature, we iterated through paper prototypes and three design pre-tests, detailed in Appendix B. In our initial
 339 paper prototyping iterations, participants struggled to *rank* relative preferences among options and *rate* the degree
 340 of trade-offs between them. In this study, we focus on addressing the former challenge, which pertains to preference
 341 construction.

342 3.1 'Organize-then-Vote': The Two-Phase Interface

343 3.1.1 *Justifying a two-phase approach.* The main objective of the two-phase interface is to facilitate preference con-
 344 struction and reduce cognitive load. As shown in Figure 1, the interface consists of two steps: an organization phase
 345 and a voting phase. In both phases, survey respondents can drag and drop options across the presented list.
 346

347 A *two-phase approach*. Preferences are shaped through a series of decision-making processes [7]. Two major decision-
 348 making theories informed this two-step interaction interface design: Montgomery [64]'s Search for a Dominance
 349 Structure Theory (Dominance Theory) and Svenson [65]'s Differentiation and Consolidation Theory (Diff-Con Theory).
 350 The former suggested that decision-makers prioritize creating dominant choices to minimize cognitive effort by
 351 focusing on evidently superior options [64]. The latter described a two-phase process where decisions are formed by
 352 initially *differentiating* among alternatives and then *consolidating* these distinctions to form a stable preference [65].
 353 Both theories supported the design decision to reduce the dimensions during the initial decision process and help
 354 emphasize relatively important options to form decisions. Hence, the two-phase design – organize-then-vote – aimed
 355 to facilitate this cognitive journey explicitly. The first phase focused on differentiating and identifying dominant options,
 356 enabling survey respondents to preliminarily categorize and prioritize their choices. The second phase presented these
 357

365 categorized options in a comparable manner, with drag-and-drop functionality, enhancing one's ability to consolidate
 366 preferences. This structured approach aimed to construct a clear decision-making procedure that reduced cognitive
 367 load and enhanced clarity and confidence in the decisions made.
 368

369 *Phase 1: Organization Phase.* The goal of the organization phase was to support participants in identifying clearly
 370 superior options or partitioning choices into distinguishable groups. In this section, we first describe how the interaction
 371 works, then we detail the reasons for the implemented design decisions.
 372

373 The organizing interface, depicted on the top half of Figure 1, sequentially presents each survey option. Participants
 374 select a response among three ordinal categories – “Lean Positive”, “Lean Negative”, or “Lean Neutral”. Once selected,
 375 the system moves that option to the respective category. Participants can skip the option if they do not want to indicate
 376 a preference. Options within the groups are draggable and rearrangeable to other groups should the participants wish.
 377

378 To support preference formation, respondents are shown one option at a time, allowing them to either recall a prior
 379 judgment or construct a new one based on the presented choices [66]. Limiting the information presented this way also
 380 helps reduce cognitive load by preventing overload from too many options [67]. This incremental process ensures that
 381 participants form opinions on individual options, addressing an early prototype issue where the organizing task was
 382 mistakenly treated as a ranking task.
 383

384 The three possible options – Lean Positive, Lean Neutral, and Lean Negative – aim to scaffold participants in
 385 constructing their own choice architecture [68, 69], which strategically segments options into diverse and alternative
 386 choice presentations while avoiding biases from defaults. We believed that these three categories were sufficient for
 387 participants to segment the options. We do not limit the number of options one can place in each category to prioritize
 388 user agency, allowing participants full control over how they organize their preferences [70]. Immediate feedback
 389 displays the placement of options and allows participants to rearrange them via drag-and-drop, adhering to key interface
 390 design principles [70]. At the same time, it allows finer-grain control for individuals to surface dominating options and
 391 create differentiating groups of options.
 392

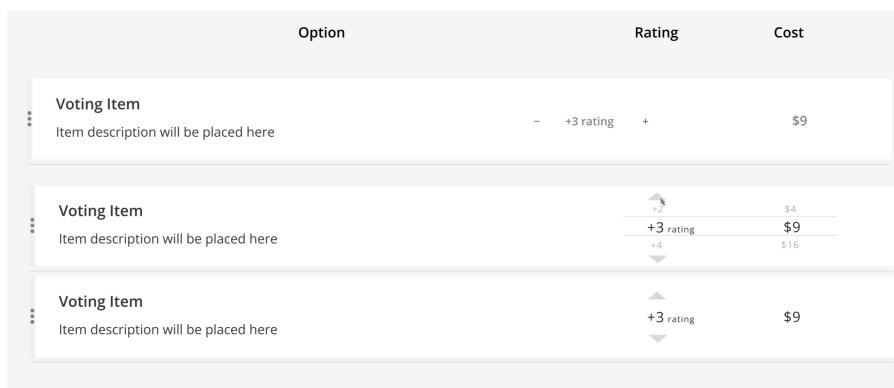

393 *Phase 2: Interactive Voting Phase.* The objective of the voting phase is to facilitate the consolidation of differentiated
 394 options through interactive elements while reinforcing the differentiation across options constructed by participants in
 395 the previous phase. This facilitation is achieved by retaining the drag-and-drop functionality for direct manipulation of
 396 position and enabling sorting within each category.
 397

398 Options are displayed as they are categorized within each category from the previous step and in the following
 399 section – Lean Positive, Lean Neutral, Lean Negative, and Skipped or Undecided – as detailed on the bottom half of
 400 Figure 1. The Skipped or Undecided category contains options left in the organization queue, possibly because survey
 401 respondents have a pre-existing preference or chose not to organize their thoughts further. The original order within
 402 these categories is preserved to maintain and reinforce the differentiated options. This ordering sequence mitigated
 403 early prototype concerns where uncategorized options were left at the top of the voting interface confusing survey
 404 respondents. Respondents have the flexibility to return to the organization interface at any point during the survey to
 405 revise their choices.
 406

407 In the voting interface, options are draggable, allowing participants to modify or reinforce their preference decisions
 408 as needed. Each category features a sort-by-vote function for reordering within the group, which, although it doesn't
 409 affect the final outcome, supports information organization and consolidation. Both features aim to group similar
 410 options automatically and emphasize proximity, reducing cognitive load by following the proximity compatibility
 411 principle to enhance decision-making [71].
 412

417 While multiple interaction mechanisms exist, drag-and-drop has been extensively explored in rank-based surveys.
 418 For instance, Krosnick et al. [72] demonstrated that replacing drag-and-drop with traditional number-filling rank-based
 419 questions improved participants' satisfaction with little trade-off in their time. Similarly, Timbrook [73] found that
 420 integrating drag-and-drop into the ranking process, despite potentially reducing outcome stability, was justified by the
 421 increased satisfaction and ease of use reported by respondents. The trade-off was deemed worthwhile as QS did not
 422 use the final position of options as part of the outcome if it significantly enhanced user satisfaction and usability [74].
 423 Together, these design decisions led to our belief that a two-phase interface with direct interface manipulation could
 424 reduce the cognitive load for survey respondents to form preference decisions when completing QS.

425 In addition, we made three aesthetic design decisions. First, we removed visual elements like icons, emojis, progress
 426 bars, and vote visualizations, as prior research indicated that emojis could influence survey interpretations and reduce
 427 user satisfaction [75, 16]. While effective visualizations can aid decision-making, this study does not aim to address that
 428 question. Second, the final interface has all options presented on the screen at the same time, intentionally. Unlike all
 429 the prototypes and existing interfaces, prior literature emphasized the importance of placing all the options on the same
 430 digital ballot screen to avoid losing votes. This echoes the proverb "out of sight, out of mind," where individuals might
 431 be biased toward options that are shown to them, and additional effort is required for individuals to retrieve specific
 432 information if options are hidden. Last, we decided to use a dropdown positioned to the right of each survey option for
 433 ease of access to the budget summary when determining the votes. The layout of the votes and cost was inspired by
 434 online shopping cart checkout interfaces where quantities are supplied next to the itemized costs followed by the total
 435 checkout amount. After testing two alternatives (Figure 3) input methods—click-based buttons, which required multiple
 436 clicks, and a wheel-based design, which offered intuitive control but was unfamiliar to some participants—we opted for
 437 a more accessible dropdown menu for vote selection.

458 Fig. 3. Alternative vote control. The click-based design (upper) mirrors traditional vote control used in other QV interfaces, where
 459 each click controls one vote. The wheel-based design (the latter two) allows control through both clicks and mouse wheel rotation.

463 3.2 Baseline Interface: Single-Phase Text Interface

464 We designed the single-phase text interface (referred to as text interface for short) as our control condition to compare
 465 how the interactive components influenced participants' cognitive load and behavior. The text-based interface includes
 466 all the functionalities of the two-phase interface except for the two-phase interactive design and drag-and-drop

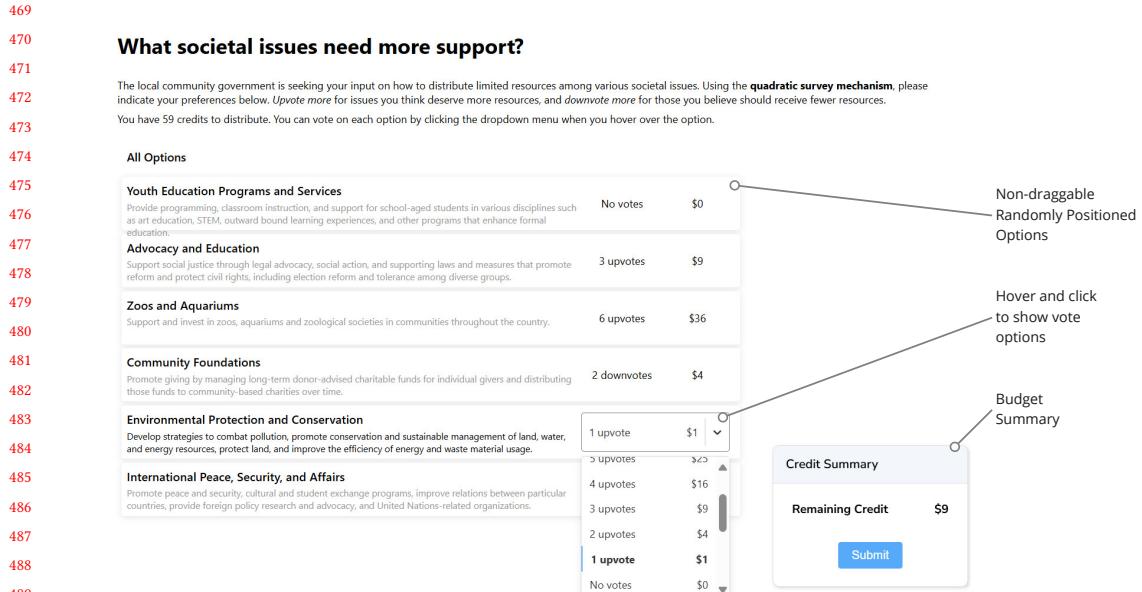

Fig. 4. The text-based interface: This interface is based on the interactive version but does not include the two-phase interactive support and lacks the drag-and-drop functionality. Options are randomly positioned.

feature (Figure 4.) The interface displays the question prompt at the top of the screen. The options appear in a list underneath the prompt. Survey can update their votes by selecting from a dropdown that lists all possible voting options and costs, based on the number of available credits. A small summary box on the right of the interface displays the current total cost and the remaining credits for the respondent. The interface randomly presents options to prevent ordering bias [76, 77].

Both experimental interfaces were developed with a ReactJS frontend and a NextJS backend powered by MongoDB. We open-source both interfaces.¹

4 Experiment Design

We recruited 41 participants, with one excluded² due to data quality concerns, from a United States college town using online ads, digital bulletins, social media posts, online newsletters, and physical flyers in public spaces beyond campus. To ensure participant diversity, we prioritized non-students by selectively accepting them as we monitored demographics. Study participants' mean age was 34.63 years old, with an age distribution similar to the county's demographic profile (Figure 5a) albeit a slightly higher representation of younger adults. Gender and race demographics are aggregated in Figure 5b and 5c. The study was framed as focusing on societal attitudes to avoid response bias. The university's Institutional Review Board reviewed and approved this study.

¹link-to-github

²The participant reported not completing the survey seriously because they believed the experiment was fake.

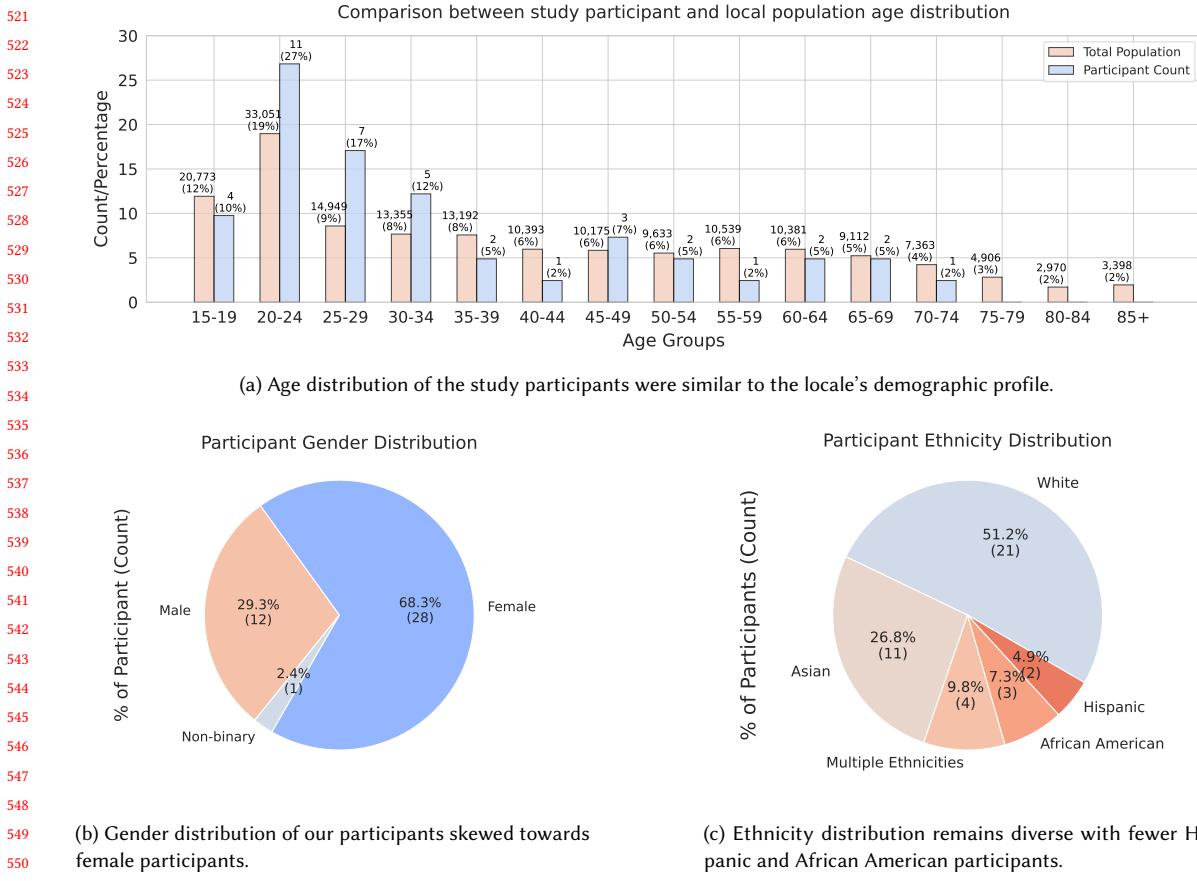

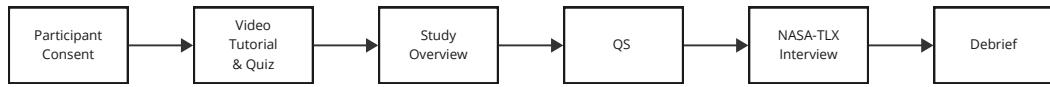

Fig. 5. Demographic distributions: Age, Gender, and Ethnicity

561 Fig. 6. Study protocol: Participants are asked to learn about the mechanism of QS after consenting to the study. The researcher
562 explained the study overview and asked participants to complete the QS. A NASA-TLX survey followed by interviews to understand
563 participants' cognitive load. We debriefed participants after the study.

564
565
566 Figure 6 visually represents the study protocol. Participants completed the study in the lab to control for external
567 influences. Participants used a 32-inch vertical monitor displaying all options. After consenting, participants watched a
568 video explaining the quadratic mechanism without hints of interface operation followed by a quiz to ensure under-
569 standing. Participants rewatched the video or consulted the researcher until they could select the correct answers. The
570 participant's screen was captured throughout the study. The researcher primed the participant that the study aimed to
571

573 help local community organizers understand preferences on societal issues to better allocate resources. Participants
 574 were randomly assigned to one of four groups:
 575

- 576 • Short Text (ST): A text interface with 6 options. ($N = 10$)
- 577 • Short Two-Phase (SP): A two-phase interface 6 options. ($N = 10$)
- 578 • Long Text (LT): A text-based interface 24 options. ($N = 10$)
- 579 • Long Two-Phase (LP): A two-phase interface with 24 options. ($N = 10$)

582 Participants completed the survey independently, without the researcher's presence. They then contacted the
 583 researcher for the NASA-TLX survey, followed by a short audio-recorded semi-structured interview. The session
 584 concluded with a debriefing and a \$15 cash compensation, during which participants were informed of the study goal
 585 on cognitive load and interface design.
 586

588 We made several experimental design choices. First, we selected a between-subject design to minimize study fatigue,
 589 considering the complexity of QS, and avoiding the learning effect that could influence how participants evaluated the
 590 options. Second, we chose the context of public resource allotment, where participants expressed their preferences
 591 regarding their preference across 6 or 24 societal issue options, following the methodology of Cheng et al. [4]. These
 592 issues are relevant to all citizens and effectively demonstrate the need to prioritize limited public resources. We curated
 593 26 societal issues used by Charity Navigator [78] which evaluates over 20,000 charities in the United States. The
 594 interface randomly presents options from this list to participants. Appendix C contains the full list.
 595

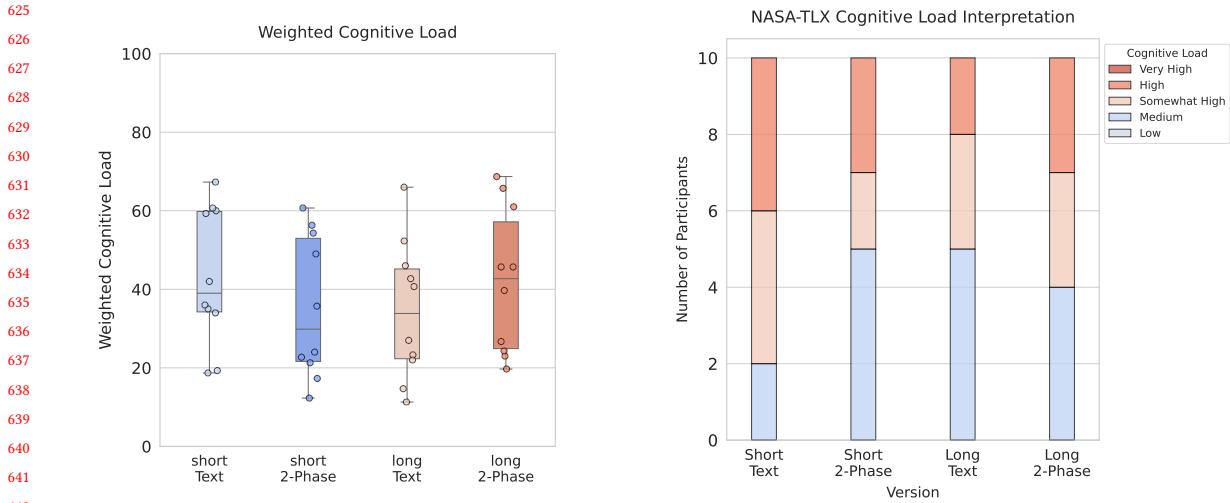

597 We decided to test 6 and 24 options, representing short and long lists, as identifying the 'breaking point' for cognitive
 598 overload would require impractical time and resource commitments. Constant sum surveys and the Analytic Hierarchy
 599 Process (AHP) recommend fewer than ten and seven options, respectively [79, 80, 81]. Miller [82]'s classic work on
 600 cognitive processing capacity and Saaty and Ozdemir [83]'s theoretical proof supported the use of 7 ± 2 items. A
 601 meta-analysis by Chernev et al. [84] identified 6 and 24 as common values for short and long lists in choice overload
 602 studies, rooted in the original experiment by Iyengar and Lepper [59].
 603

604 Finally, we deployed self-report subjective surveys and analytical measures (i.e., time and clickstream data). We
 605 adopted the paper-based weighted NASA Task Load Index (NASA TLX), a widely used multidimensional tool that
 606 averages six subscale scores to represent overall workload after completing a task [85, 86, 87]. NASA-TLX is favored for
 607 its low cost and ease of administration [88], with less variability compared to one-dimensional workload scores [89],
 608 making it suitable for our study. Given the extended nature of QS, we did not choose to measured cognitive load using
 609 performance measures, psychophysiological measures, subjective measures, and analytical measures [88].
 610

613 5 Cognitive Load and Sources across Experiment Conditions

615 This section presents cognitive load across experiment groups and the sources contributing to each cognitive load
 616 dimension. Due to the smaller sample size, we focus on descriptive statistics and qualitative assessments. We present
 617 quantitative data from survey tasks and qualitative insights from post-survey interviews.
 618

619 The first author conducted an inductive thematic analysis [90] after transcribing the interviews. Snippets were coded
 620 based on research questions and topics of interest, and similar codes were merged to form themes. When differences
 621 emerged across experiment conditions and hypotheses were formed, the first author applied a deductive coding process
 622 to the relevant text snippets. We begin by presenting an overview of the cognitive load findings.
 623

(a) NASA-TLX Weight Score: The Long Two-Phase Interface exhibits the highest weighted cognitive load with a median of 42.70, a mean of 42.02. This is higher than the long text interface, which has a median cognitive load of 33.85 and a mean of 34.60. However, the short text interface demonstrates a higher cognitive load with a median of 39.00, a mean of 43.23, compared to the short two-phase interface, which has a median of 29.85, a mean of 35.36. The standard deviation is similar across groups at around 18.

(b) NASA-TLX Cognitive Interpretation: More participants in the short text interface, totaling 8, reported a somewhat high or above cognitive load, which is significantly higher compared to the 5 participants who reported similarly for the short two-phase interface. However, the long two-phase interface saw slightly more participants, 6 in total, reporting somewhat high or above cognitive load compared to the long text interface.

Fig. 7. This figure shows the box plot results for weighted NASA-TLX scores across experiment groups and participant counts based on individual score interpretations. In 7a, we observe a downward trend in cognitive load for the short QS, while the long QS shows an upward trend. Interestingly, there is a counterintuitive downward trend between short and long text interfaces. In 7b, these trends are clearer when NASA-TLX scores are grouped into five tiers.

5.1 Overall Cognitive Load

To answer our research question on how the number of options in QS (**RQ1**) and the interface (**RQ2a**) impacted cognitive load, we derive the weighted NASA-TLX scores across the four experiment conditions. We show these results in Figure 7. Weighted NASA-TLX uses a continuous 0-100 score, with higher values indicating greater cognitive load. We use predefined mappings of NASA-TLX scores to cognitive levels: low, medium, somewhat high, high, and very high, as listed by Hart and Staveland [85]. We show value interpretations in Figure 7b.

Surprisingly, the long text interface had lower mean ($\mu = 34.60$) and median ($\tilde{x} = 33.85$) cognitive load scores than both the short text ($\mu = 43.23$, $\tilde{x} = 39.00$) and long two-phase interfaces ($\mu = 42.02$, $\tilde{x} = 42.70$). Additionally, the two-phase interface decreased cognitive load for the short survey but increased it for the long survey. Notably, the short text interface had the most participants ($N = 8$) reporting somewhat high or higher cognitive loads. In contrast, the other conditions had a more balanced distribution, with about half reporting medium to high loads.

We acknowledge that these results may not fully reflect actual cognitive load due to potential noise from factors such as small sample size, task nature, or participants' interpretation of the scale. To explore the similarities and sources of cognitive load across interfaces (**RQ2b**), we turn to qualitative insights from post-task interviews based on NASA-TLX

⁶⁷⁷ cognitive load dimensions. Among the six NASA-TLX dimensions, we focus on mental demand, temporal demand, and
⁶⁷⁸ frustration while summarizing key findings regarding physical demand, performance, and effort for brevity. Appendix D
⁶⁷⁹ provides further details on all six dimensions.
⁶⁸⁰

⁶⁸¹

⁶⁸² 5.2 Sources of Mental Demand

⁶⁸³

We began by examining mental demand, which refers to the amount of mental and perceptual activity required to
⁶⁸⁴ complete a task. Interview results indicated that the primary drivers of participants' mental demand were *Budget*
⁶⁸⁵ *management* and *Preference construction*.
⁶⁸⁶

⁶⁸⁷

⁶⁸⁸ 5.2.1 *Mental Demand Source #1: Budget management.* 14 participants expressed demand from budgeting within limited
⁶⁸⁹ credit (*S032 Q [...] for certain societal issues you had to ... take away from other societal issues that you could support.*,
⁶⁹⁰ *N = 5*), tracking remaining credits (*S006 Q [...] looking at the remaining credits, I'm trying to mentally divide that up*,
⁶⁹¹ *before I start allocating*, *N = 10*), and maximizing credit use (*S032 Q [...] I used all the credit that I had available*,
⁶⁹² *N = 8*).
⁶⁹³

⁶⁹⁴

We categorized budget management-induced mental demand as either operational (single interface-level action,
⁶⁹⁵ e.g., using the last remaining credit) or strategic (higher-level goal, e.g., evenly distributing credits across options).
⁶⁹⁶ Participants who completed longer surveys more frequently reported operational causes, suggesting that an increase in
⁶⁹⁷ survey options induced short-term thinking.
⁶⁹⁸

⁶⁹⁹

⁷⁰⁰ 5.2.2 *Mental Demand Source #2: Preference construction.* All but one participant reported increased mental demand
⁷⁰¹ due to preference construction. We further break it down into three sources: comparative preference evaluation (i.e.,
⁷⁰² evaluating relative importance between options; *S002 Q Figuring out ... how much I prioritize option 1 over option 2*,
⁷⁰³ *N = 16*), resource-constraint prioritization (i.e., trading off between options due to resource constraints, *S005 Q [...]*
⁷⁰⁴ *very hard to take decisions ... because I felt that multiple options deserve equal amount of credit ... but you have given very*
⁷⁰⁵ *limited amount of credit.*, *N = 17*), and deciding the exact number of votes (*S023 Q [...] having to pick how many*
⁷⁰⁶ *upvotes would go to each one*, *N = 30*).
⁷⁰⁷

⁷⁰⁸

Almost all participants mentioned preference construction as a source of mental demand, supporting our claim that
⁷⁰⁹ preference construction when completing QS is a difficult and mentally demanding task. Notably, more participants
⁷¹⁰ using the text interface reported mental demand from deciding the exact number of votes compared to the two-phase
⁷¹¹ interface (18 vs. 12). We conjecture that the first pass on the survey items and organizing them helped participants
⁷¹² construct preliminary preferences and reduced their mental demands when they started allocating votes.
⁷¹³

⁷¹⁴

In addition, when categorizing preference construction-induced mental demand, participants (*N = 8*) in the long text
⁷¹⁵ interface tend to consider a smaller scope that focuses on personal relevance. Conversely, participants (*N = 9*) in the
⁷¹⁶ long two-phase interface considered the broader societal impact and evaluated options more comprehensively. Compare
⁷¹⁷ the following two quotes, where one focused on adjusting credits between two options and the other reflecting across
⁷¹⁸ broader societal values:
⁷¹⁹

⁷²⁰

Trying to figure out what upvotes I should give [...] went back and forth between those two. [...] it was very mentally tasking for me.
⁷²¹ *Q S015 (LT)*

⁷²²

[...] really having to think, especially with so many different societal issues. How do I personally prioritize them? And to what extent
⁷²³ *do I prioritize them?* *Q S009 (LI)*

⁷²⁴

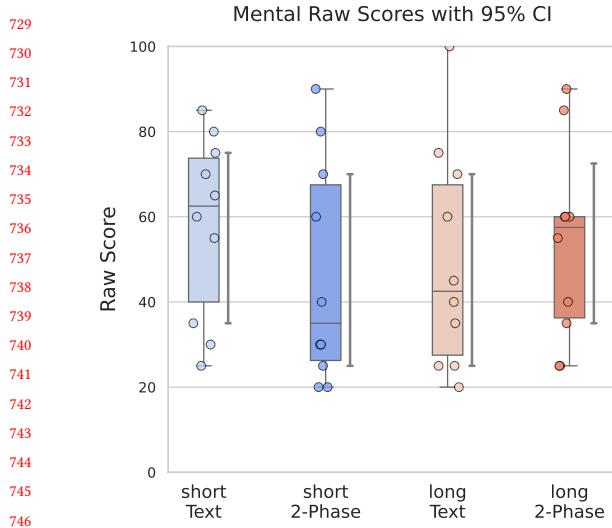

Fig. 8. Mental Demand Raw Score: Across all four experiment groups, participants' reported mental demand is spread across a wide range with many participants experiencing high mental demand.

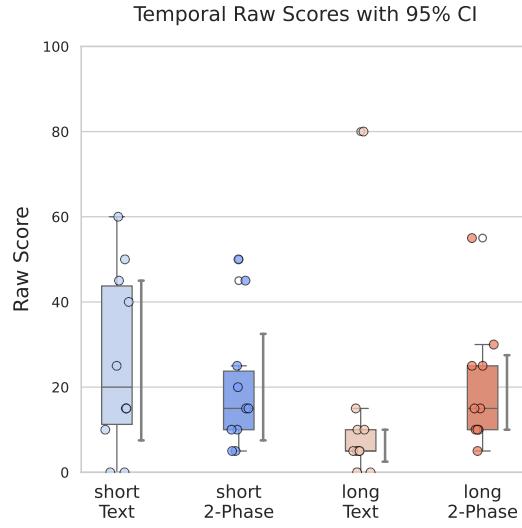

Fig. 9. Temporal Demand Raw Score: The short text interface results in the highest temporal demand, while the long text interface is the lowest. Two-phase interfaces show moderate temporal demand, suggesting that interactive elements allowed participants to pace themselves better.

Inspecting both causes, we did not notice significant differences in mental demand raw values (Figure 8) across the four experiment groups, especially between the interfaces across long QS. However, the experiment groups' mental demands came from different sources.

5.3 Sources of Temporal Demand

Temporal demand measures the time pressure participants feel during a task. Lower demand indicates participants taking a more leisurely pace. The main sources of increased temporal demand relate to time pressure on *Decision-Making* (S024 *maybe I should just hurry up and make a decision*, $N = 15$) and *Operational Tasks* (S032 *to be able to move through this quickly and efficiently*, $N = 16$) (Table 5). Additionally, some participants mention *Budget management* as a source of temporal demand (S034 *as the money decreases I felt kind of rushed*, $N = 4$).

5.3.1 Two-phase Interface Reduced Temporal Demand on Short QS. The raw NASA-TLX values in Fig 9 show that participants in the short text interface reported the highest temporal demand. Five participants expressed concerns about time spent on decision-making, feeling themselves invested more time and effort than expected, prompting them to rush. However, the two-phase interface reduced this, with only one participant in the short survey group reporting similar concerns.

5.3.2 Long QS on Text Interface Showed the Lowest Temporal Demand. Surprisingly, participants in the long text interface exhibited the lowest temporal demand (Fig. 9) despite making more decisions and operations compared to the short text group. Two possible explanations might explain this counter-intuitive result. First, more participants in the short survey group ($N = 7$) expressed a desire to complete the task efficiently, compared to just one participant ($N = 1$) in the long survey group, saying things like:

781 *I wanna get through things in an efficient manner [...] to move through this quickly and efficiently.*

782 S032 (ST)

783 Second, satisficing behaviors may explain the lower temporal demand in the long text condition. Participants may
 784 have experienced cognitive overload from the long list of options and, as a result, spent less time than expected on
 785 decisions. For example:

786 *I didn't really do the math, so I was like \$2 is not that much left so I tried my best to use up most of it.*

787 S035 (LT)

788 We will discuss this possibility further in Section 7.1.

789 5.3.3 *Two-phase Interface Increased Temporal Demand in Long QS.* Despite the unexpectedly low temporal demand
 790 in long QS with a text interface, two-phase interface participants have indifferent temporal demand across survey
 791 lengths. All five participants who mentioned a feeling of time pressure on decision-making in the long two-phase group
 792 described the pressure affirmatively. This means their pressure stemmed from having too many remaining decisions
 793 to make (S022 *So it didn't take too much time, but obviously there were a lot of things to consider, so there was some*
 794 *temporal demand.*), not from the time they have already spent (i.e., framed negatively) as that in the short text group.
 795 S022
 796 S022
 797 S022
 798 S022

799 5.4 Source of Frustration

800 Frustration refers to the extent to which the participant is annoyed, irritated, or discouraged during the task. We identified
 801 either *Operational Actions* (e.g., credit management ($N = 6$)
 802 and managing quadratic vote costs ($N = 5$)), or *Societal Concerns* (e.g., regretful trade-offs ($N = 8$) or pessimism about
 803 other's vote ($N = 6$)) as sources of frustration.

804 In general, the frustration derived from societal concerns
 805 did not seem strongly affected by any of the experimental conditions. We saw some discrepancies with respect to operational
 806 action-driven frustration. The long text interface condition had
 807 the fewest participants expressing operational frustration, with
 808 half expressing no frustration, mirroring the trends in the actual
 809 scores (Figure 10). Similar to the finding that the long text group
 810 has the lowest temporal demand, this is counter-intuitive as
 811 more options and dense text are known to lead to more frustra-
 812 tion in interface design [91]. Participants engaging in satisficing
 813 behaviors in the long text interface may explain this phenom-
 814 enon – prior literature [92, 93] indicates that satisficers tend
 815 to be less frustrated and happier than maximizers.

816 5.5 Physical Demand, Effort and Performance

817 Physical demand refers to the physical effort required to complete a task, such as physical exertion or movement. The
 818 two-phase interface experienced higher physical demand from increased mouse usage.

819 Effort refers to how hard participants felt they worked to achieve the level of performance they did. Qualitative analysis
 820 showed participants using the two-phase interface, regardless of length, considered options more comprehensively and
 821 Manuscript submitted to ACM

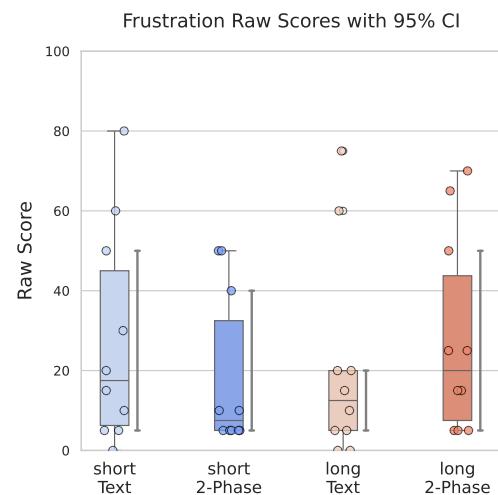

Fig. 10. Frustration Raw Score: Participants other than the long text interface highlighted several operational tasks that led to frustration. All groups share causes from strategic planning.

833 felt less effort in completing operational tasks. Almost all participants ($N = 9$) from the long two-phase interface spent
834 effort planning a strategy to complete tasks with many ($N = 7$) considered options comprehensively and beyond the
835 immediate task (i.e., considering the broader community impact of their choices).

836 Performance refers to a person's perception of their success in completing a task. An interesting element that
837 contributed to their cognitive load comes from concerning social responsibility. They wonder how their final vote
838 counts would be perceived by others (S041 *I don't want people to think that I just like don't care about <ethnicity>*
839 *people at all*) or influence real-world decision-making (S027 *Some of these things might ... have outcomes that I didn't*
840 *foresee*). In addition, when analyzing how participants describe their performance, we categorize them into indications
841 of satisficing behaviors ("good enough"), exhausting their effort (i.e., "done their best"), or feeling positive (i.e., "feeling
842 good.") We observed twice as many participants using the two-phase interface to report the positive feeling about their
843 final submission ($N = 11$ v.s. $N = 6$).
844

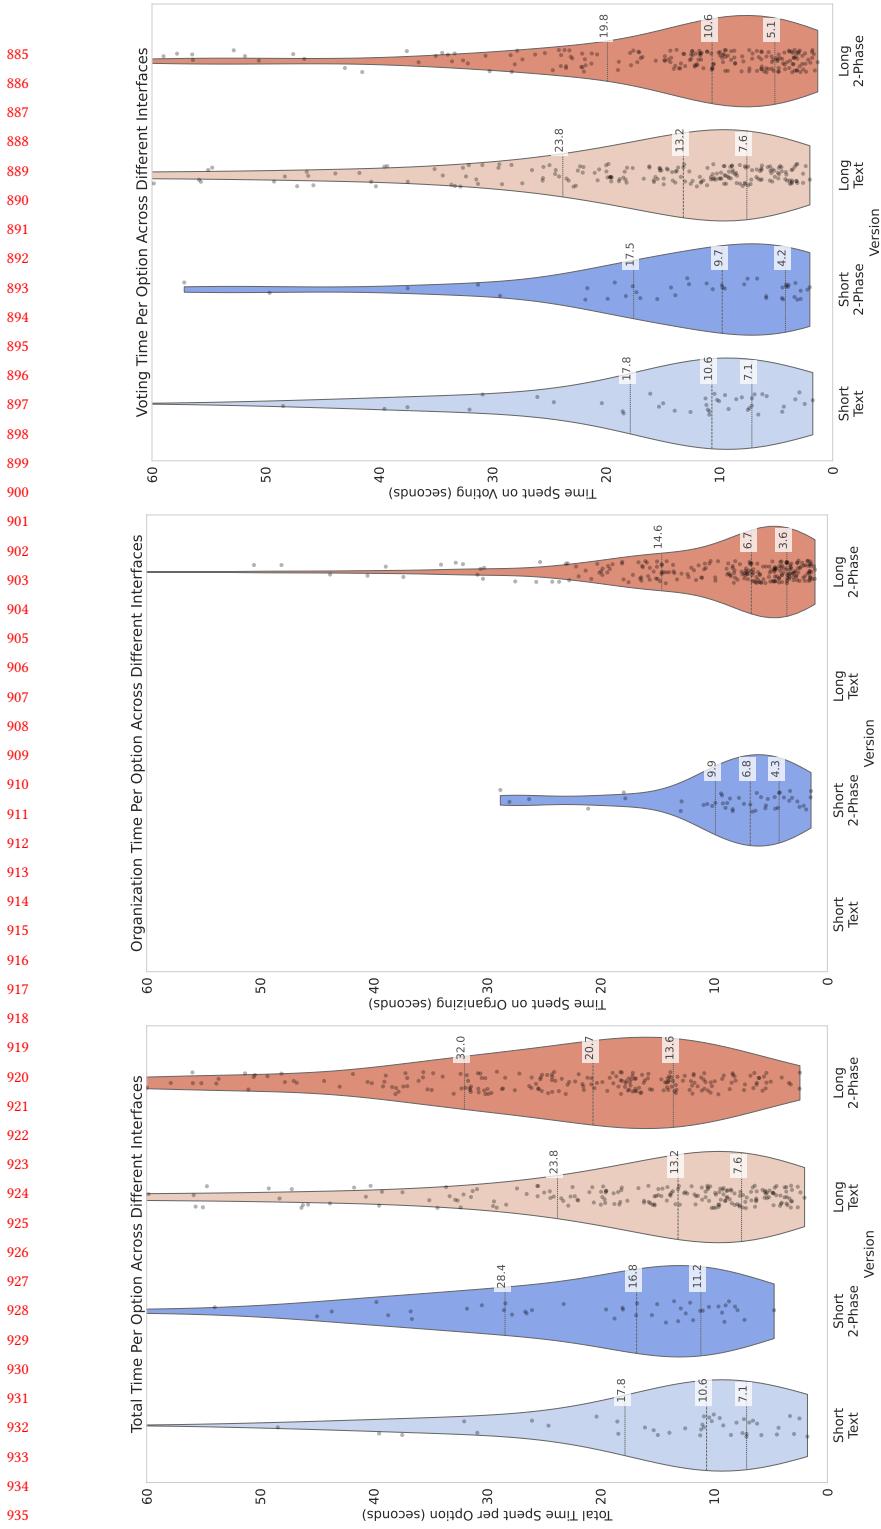

845 5.6 Summary across all cognitive load dimensions

846 Overall, participants using the two-phase interface tended to think more comprehensively and critically, while those
847 using the text interface focused more on operational tasks. This is reflected by *mental demand* findings where parti-
848 cipants using the text interface reported greater difficulty in determining the precise number of votes. In contrast,
849 participants using the long two-phase interface were more likely to consider broader societal impacts and evaluate
850 options holistically. *Effort* echoes similar findings. In terms of *physical demand*, participants using the two-phase
851 interface, particularly in longer surveys, experienced higher demand due to increased mouse usage, which was expected.
852 Additionally, participants using the short text interface wanted to complete the task quickly and reported the highest
853 *temporal demand*, while those using the long text interface reported the lowest. Moreover, participants using the
854 long text interface exhibited the least amount of *frustration* from operational causes compared to other experimental
855 conditions. Thus, we suspect that participants who completed the long QS on a text interface engaged in satisficing
856 behaviors, based on the counter-intuitive results showing they had the lowest temporal demand and frustration levels.
857 Finally, in relation to *performance*, participants using the two-phase interface more frequently reported positive feelings
858 about their final submissions, suggesting greater confidence in their decision-making process. We will interpret these
859 results in the discussion section. To better understand participants' behavior, we analyze click-stream data across
860 experimental conditions in the next section.
861

862 6 Behavior Results

863 To understand how interfaces and options influenced survey response behaviors (RQ3), we investigate time-to-action
864 and remaining credit differences across experiment conditions. Time-to-action is a widely used metric in decision
865 sciences, where longer decision time often indicates more complex cognitive processing [94]. Additionally, resource
866 allocation strongly influences decision-making. Cheng et al. [4] showed that the number of given credits influences the
867 validity of QV. Decision science studies like Shah et al. [95] and [96] showed how scarcity influences decisions, increases
868 risk aversion, and adds cognitive load. These measures serve as proxies for participant behavior, and all analyzed data
869 is publicly available³ for transparency and to facilitate further research.
870

884

- (a) Total Time per option: We identified that the two-phase interface was slightly higher than the text interface, as expected. This discrepancy can be attributed to the extra organization step required in the two-phase interface, leading to a slightly longer overall completion time per option.
- (b) Organization Time per option: Only the two-phase interface includes an organization phase, hence the other experimental conditions do not exhibit any accumulated organization time. This figure reinforces that organization time was isolated to the two-phase design.
- (c) Voting Time per option: We observe statistically significant faster voting times for the long QS in the two-phase interface. This suggests that the two-step design improves voting efficiency, especially for longer surveys.

Fig. 11. Time per option across all experiment conditions. The violin plots visualize time spent per option across the experimental conditions, with dots representing total time per option and horizontal lines indicating the median and interquartile ranges. While total time was slightly higher for the two-phase interface, the distinct phases (organization and voting) allowed for a more structured approach, particularly benefiting longer surveys.

937 **6.1 Time Spent per Option**

938 Our first analysis focuses on understanding how much time participants spent per option across different stages and
 939 experiment conditions. Based on the QS system log, we extracted the following detail: *the option* involved in the
 940 interaction, *the type of interaction* (such as updating a certain number of votes), and *the time* between this interaction
 941 and the previous one. Each dot on Figure 11 is a specific type of time a participant spent for one option.
 942

943 *Total time.* Total time is the aggregate of all time spent on each option across both phases. Each dot on Figure 11a
 944 visualizes the total time. Participants spent slightly more time per option on the two-phase interface than the text
 945 interface. A non-parametric Mann-Whitney U test showed a small effect size (long QS: $p < 0.0000001$, Rank-biserial:
 946 -0.304 , Cohen's d: 0.030; short QS: $p = 0.01$, Rank-biserial: -0.37 , Cohen's d: 0.082). This is expected as the two-phase
 947 interface has an additional step of organizing the options.
 948

949 We further break down the total time spent into organization time and voting time. To minimize noise, we intentionally
 950 dropped all the time participants spent on the first option in the organization phase or voting phase. The goal is to
 951 exclude time spent on reading the prompt, forming their preference, or understanding the interface.
 952

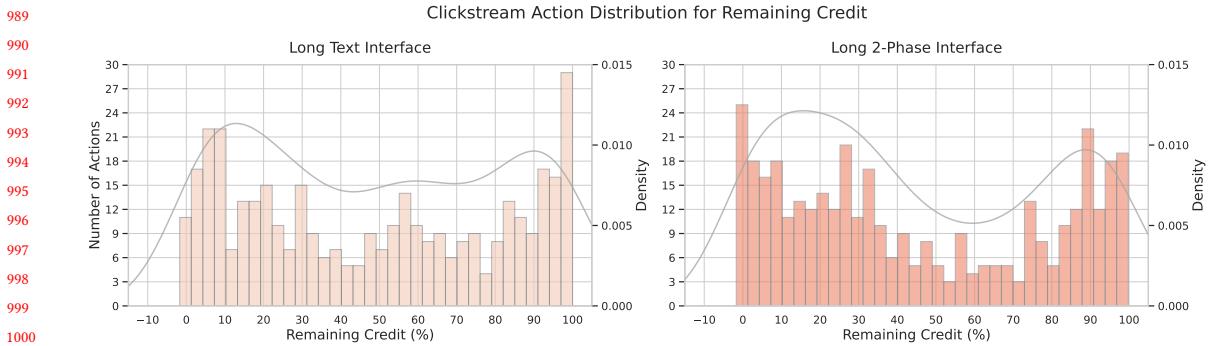

953 *Organization time.* Organization time covers both placing options into categories and the drag-and-drop time during
 954 the organization phase. Illustrated in Figure 11b, we observed minimal difference in organization time per option
 955 between short and long surveys, as the interface shows options one at a time for categorization. It also suggests that
 956 even for longer surveys, the organization functionalities did not significantly impact the time participants needed for
 957 an option.
 958

959 *Voting time.* Voting time strictly refers to the time participants took to update vote values for each option. As shown
 960 in Figure 11c, participants spent significantly less time voting on the two-phase interface than on the text interface
 961 with a small effect size in the long QS ($U = 24053$, $p < 0.005$, Rank-biserial: 0.167, Cohen's d: 0.017), but not in the
 962 short survey ($p > 0.4$, Power=0.051). This supports our hypothesis that the two-step design in the two-phase interface
 963 facilitates more efficient decision-making, especially in longer surveys.
 964

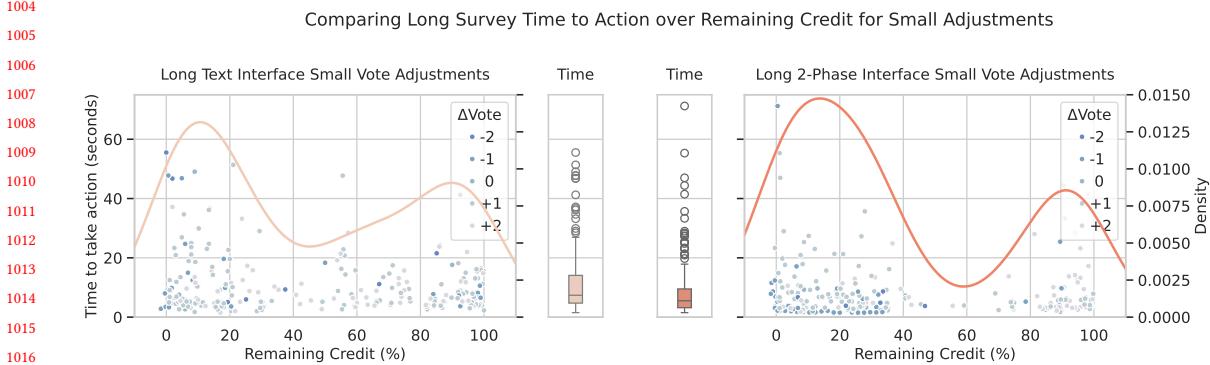

965 **6.2 Budget and Voting Behaviors**

966 We further breakdown and highlight key differences of how long QS participant's voting behaviors when credits changed
 967 their voting behaviors with detailed analysis in Appendix F. Figure 12a first shows the number of vote adjustments
 968 at a given remaining budget across the two interfaces. We then plotted the vote adjustments of two or fewer votes,
 969 which is 10% of the possible values one can choose among the maximum of 21 votes in Figure 12b. A kernel density
 970 estimate (KDE) plot is provided to visualize the trends and compare how it changed when we plotted only small vote
 971 adjustments.
 972

973 In long surveys, participants exhibited more actions both when the budget was abundant and when it began to run
 974 out. This pattern was more pronounced with the long two-phase interface. In fact, the bimodal distribution is more
 975 pronounced in the two-phase interface. This suggests that participants make small adjustments both at the beginning
 976 and toward the end of the QS. However, the two-phase interface shows more frequent and faster edits towards the
 977 end. Visually, dots are more clustered in the long two-phase interface for small vote adjustments compared to the long
 978 text interface. The Mann-Whitney U Test on the time spent on small vote adjustments showed significant differences
 979 ($U = 13037$, $p < 0.001$), with a small effect size (Rank-biserial: 0.227, Cohen's d: 0.195) and a power of 0.381. This
 980 indicates that participants had a clearer idea of how to distribute their credits across the options.
 981

(a) This plot counts the number of voting actions when there are x percentages of credits remaining. A KDE plot is provided to help better understand the action distribution.

(b) This plot further separates participants' interaction behavior based on the number of votes participants adjusted. We observed a bimodal interaction pattern across long QS when small vote adjustments are made.

Fig. 12. Comparison of voting actions and participant behavior in different survey interfaces. Subplot (a) shows the overall distribution of actions based on the remaining credit, while subplot (b) further differentiates the interaction based on the size of vote adjustments.

Five participants highlighted how the interface supported their incremental iterative approach during the interview whom all used the two-phase interface. As one participant pointed out:

I like the fact that it remembers everything that you know. [...] that's very important is that it's an iterative process. S019 (LI)

In summary, participants spent more time on the two-phase interface compared to the text interface in both short and long surveys. Across the two-phase interfaces, organization time remained consistent. While voting time did not differ between interfaces for the short survey, participants voted more quickly on the two-phase interface in the long survey, confirming the hypothesis that the two-step design enhances decision-making efficiency. Voting behaviors indicated more frequent actions when the budget was abundant and nearly exhausted, particularly in the long two-phase interface. Additionally, the analysis revealed more frequent and faster small vote adjustments towards the end of the QS in the two-phase interface, demonstrating an iterative and incremental approach.

1041 7 Discussion and Future Works

1042 In the discussion section, we interpret results related to cognitive load and survey respondent behaviors. Specifically,
1043 we aim to understand why results in Section 5 revealed that long text interface participants did not experience higher
1044 cognitive load, contrary to expectations referencing prior literature and insights from Section 6.

1045 We focus on three key topics: what two-phase interface elements influenced behavior, how these elements supported
1046 preference construction, and the remaining design challenges. Additionally, we provide recommendations for using
1047 QS and suggest design improvements. We concluded that the two-phase interface prevented satisficing behaviors and
1048 promoted strategic, holistic thinking, unlike the text-based interface, which leaned toward operational tasks. Behavioral
1049 analysis showed that long two-phase interface participants made frequent, small updates, shifting their cognitive focus.
1050

1051 7.1 Interpretation of results: Two-phase interface limits satisficing during cognitive overload

1052 Participants using the long two-phase interface reported slightly higher cognitive load compared to those using the
1053 long text interface. In comparison, the short two-phase interface resulted in a lower cognitive load. This suggests that
1054 the two-phase interface alone does not inherently increase cognitive load.

1055 One explanation is that the two-phase interface reduces cognitive load in the short QS but not in the longer one. In
1056 longer surveys, the interactive nature of the two-phase interface may require participants to perform more operations
1057 without significantly altering their decision-making processes. However, our findings suggest that participants using
1058 the two-phase interface in longer surveys responded more efficiently. Across both short and long surveys, participants
1059 using the two-phase interface demonstrated iterative and efficient fine-tuning preferences, indicating deeper survey
1060 engagement. Therefore, we reject the claim that the two-phase interface increases cognitive load in the long survey.

1061 An alternative explanation is that while the two-phase interface limits satisficing during cognitive overload, the
1062 complexity of the long QS may have counteracted this effect, preventing a full reduction in cognitive load. This suggests
1063 that long QS participants resorted to satisficing behaviors to manage their cognitive overload. Qualitative results support
1064 this explanation: participants using the two-phase interface engaged in broader, more strategic considerations, while
1065 those using the text interface focused on operational tasks. For instance, participants using the long two-phase interface
1066 experienced less cognitive burden from precise voting and managed their time better. Overall, the two-phase interface
1067 participants demonstrated deeper and more critical thinking, as they engaged in more strategic decision-making.

1068 In contrast, participants using the long text interface satisficed due to cognitive overload from having to decide
1069 and allocate more credits for more options. However, fewer participants in this group reported high cognitive load
1070 compared to those in the short-text interface. This group also experienced the least temporal demand and frustration
1071 with operational tasks, despite spending a similar amount of time per option as participants using the text interface.
1072 These counterintuitive findings pointed to the remaining plausible explanation that long-text interface participants
1073 used satisficing to manage the overload.

1074 **In summary**, the interactive components of the two-phase interface likely prevented mental shortcuts [58, 10, 11,
1075 12], resulting in a cognitive *shift* towards deeper reflection and decision-making. Thus, while QS with many options
1076 might lead to satisficing, the two-phase interface redirects participants' attention, facilitating the decision-making
1077 process that promotes comprehensive preference construction. In the following section, we examine these specific
1078 elements that guided participants to achieve this.

1093 7.2 Bounded rationality and interface design

1094 Bounded rationality emerged as a core theme in participants' responses, highlighting how cognitive limitations lead to
 1095 sub-optimal decision-making due to their inability to process all available information [10]. This often led to *satisficing*
 1096 behaviors, where participants settle for *good enough* but not *optimal* decisions [97].

1097 For instance, S036 described making meaningful choices while acknowledging the limits of their effort:

1098 [...] you thought of enough things, you know, and so it wasn't the most effort I could put in because again, that would have been
 1099 diminishing returns. I tried to think of enough things [...] and then move on. [...] I felt like that (the response) was satisfied, but not
 1100 perfect. Cause perfect is not a reality. Q S036 (ST)

1101 This illustrates typical satisficing decision-making, where participants settle for suboptimal choices. In long QS, the
 1102 significant increase in decision points—due to the numerous vote and credit options—was so overwhelming to some
 1103 that even features like pre-calculated vote-credit values in drop-down menus provided relief, as they helped avoid the
 1104 cognitively demanding task of searching for bounds.

1105 Participants often relied on *heuristics* [98] and *defaults* [69], behaviors less common among two-phase interface
 1106 participants. Presenting one option at a time reduced reliance on defaults and encouraged deeper reflection, as illustrated
 1107 by S013, who highlighted how the organization phase supported their option preferences construction:

1108 [...] it (organization phase) gives you time to just focus on that single thing and rank it based on how you feel at that moment.
 1109 Q S013 (SI)

1110 Conversely, text interface participants, like S003, described how default placements influenced their decisions:

1111 Honestly, if medical research [...] was the first one I saw, I think it would automatically give it a lot more. Q S003 (ST)

1112 The three key elements of the organization phase—presenting options one at a time, grouping them into categories,
 1113 and enabling drag-and-drop—worked together to structure participant preferences. These elements aligned with
 1114 cognitive strategies like *problem decomposition* [99] and *dimension reduction* which reduces cognitive overload. Bounded
 1115 rationality illuminates the importance of decision-making support interfaces rather than being a critique of human
 1116 behaviors. One participant explained how the organization phase broke down complex decisions into manageable steps:

1117 [...] being able to have a preliminary categorization of all the topics. First, it introduced me to all the topics, [...] to think about
 1118 and process [...] being able to digest all the information prior to actually allocating the budget or completing the quadratic survey.
 1119 Q S009 (LT)

1120 Participants using the two-phase interface, especially in the long version, organized options along dimensions such
 1121 as topics (e.g., health vs. humanitarian) and preferences (positive vs. negative) before voting. Others expressed that
 1122 the upfront introduction of all options and the ability to rank and group them helped manage their cognitive load
 1123 effectively. In contrast, almost half of the participants using the long text interface, like S028, expressed a desire for
 1124 features that can help reduce the decision space when responding to the QS, further supporting the importance of these
 1125 organizational design elements:

1126 Because with this many (options), especially when I'm thinking ... Ok, where was (the option)... Where was (the option) you know?
 1127 Oh, that's right. Maybe I could give another up another upvote to the, you know whatever [...] Q S028 (LT)

1128 This quote reflected participants' need to manually track and revisit options, which occupies cognitive load, without
 1129 a more structured interface.

1130 **In summary**, individual's bounded rationality encouraged participants to exhibit *satisficing* behaviors, *heuristics*,
 1131 and *defaults* when responding to QS. Showing all options upfront, one at a time, and repositioning options based on partic-
 1132 ipants' rough preferences prevented participants from using defaults and heuristics. The two-phase organization actively
 1133 Manuscript submitted to ACM

1145 scaffolds participants' decision-making process, supporting efficiency *problem decomposition* and *dimension reduction*.
 1146 Together, these elements in the two-phase interface design prevented *satisficing* behaviors and supported participants
 1147 in making more informed decisions through a more strategic planning and holistic thinking process.
 1148

1149 7.3 Construction of Preference on Quadratic Survey

1151 Completing QS is a series of difficult decision tasks Lichtenstein and Slovic [7]. Svenson [65]'s differentiation and
 1152 consolidation theory helps explain how participants process these decisions. The decision process begins with dif-
 1153 ferentiation, where participants identify differences and eliminate less favorable options, followed by consolidation,
 1154 which strengthens their commitment to selected choices. This theory aligns with how the two-phase interface helps
 1155 participants decompose options into categories, effectively reducing decision complexity.
 1156

1157 Participants started by constructing preferences *in situ*, especially regarding options they hadn't previously consid-
 1158 ered:
 1159

1160 [...] 'Oh, there are other aspects that I never care about.' And actually ... some people care <an option>. Sure. Why? Why (should) I
 1161 spend money on that?
 1162 ☰ S037 (LI)

1163 Those using the text interface, lacking the interactive tools, found it challenging to facilitate differentiation as S025
 1164 noted:
 1165

1166 I would like to be able to like, click and drag the categories themselves so I could maybe reorder them to like my priorities. [...] make
 1167 myself categories and subcategories out of this list ... If I could organize it.
 1168 ☰ S025 (LT)

1169 In contrast, the two-phase interface allowed participants to express at least one dimension of differentiation more
 1170 easily. The drag-and-drop feature helped blend this differentiation into the consolidation phase. Not only does partic-
 1171 ipants drag-and-drop options post voting to reflect and assure a correct vote allocation, it also enables participants,
 1172 like S039, to make fine-grain comparisons between options:
 1173

1174 I think the system was actually really helpful because I could just drag them. [...] I can really compare them, I can drag this one up
 1175 here, and then compare it to the top one [...]
 1176 ☰ S039 (SI)

1177 The bi-modal behavior observed in the long interactive interface participants provided in the results aligns with the
 1178 differentiation and consolidation framework. Participants in the two-phase interface began differentiating options earlier
 1179 allowing them to later adjust fine-grain votes. The faster and smaller vote updates indicated participants consolidating.
 1180 The less prominent bi-modal behavior from the long text interface participants implied that the interface guided this
 1181 decision framework as participant 037 explained:
 1182

1183 I only start from the positive one [...] I finish everything ... and then I move to the second part (the neutral box). [...] I want to focus
 1184 on these and make sure that resources are at least they get the attention they want. And if there's surplus and they can move to the
 1185 second part.
 1186 ☰ S037 (LI)

1187 These evidences explain how the organization phase and the drag-and-drop features supported differentiation and
 1188 consolidation, scaffolding a decision-making framework enabling deeper engagement.
 1189

1190 **In summary**, participants construct their preferences as they complete QS. We observed behaviors and qualitative
 1191 insights that align with the differentiation and consolidation theory in decision-making. Our interface scaffolded many
 1192 of the differentiation stages through pre-voting organization and some consolidation phases through drag-and-drop,
 1193 explaining how the two-phase approach supports preference construction to yield effective QS responses.
 1194

1197 7.4 Opportunities for better budget management

1198 Budget management is a recurring theme in participant interviews. While they appreciated the automatic calculation
 1199 feature in modern QV interfaces, we identified three challenges for future QS interfaces: *cognitive load, the cold-start*
 1200 *problem, and navigating between budget, votes, and outcome.*

1203 *7.4.1 Automatic calculation is critical.* Over one-third of participants ($N = 14$) from all four experiment conditions
 1204 emphasized the importance of automated calculation for deriving costs and tracking expenditures. For example:

1206 *I thought I have [...] (to) do all the numbers or calculations myself as a part of checking my ability of doing mathematics. [...] I said*
 1207 *that credit summary to be very specific. The credit summary section was really wonderful in doing all the calculations on that end.*

1208 S005 (LT, keeping track of spent)

1210 The quotes marked the importance that QS must be facilitated by computer-supported interfaces.

1212 *7.4.2 The coldstart problem.* We notice from the study that one of the biggest challenges for participants is deciding
 1213 'how many votes' to start with. This challenge pertains to the initial vote, not the relative vote. Some participants began
 1214 by equally distributing their credits to all options and then made adjustments. Others established 1, 2, and 3 votes as
 1215 starting points. A small handful surprisingly used the tutorial's example of 4 upvotes as their anchor.

1217 This arbitrary voting decision echoes discussions in prior literature about the existence of an absolute value for
 1218 individuals. Coherent arbitrariness [100], similar to the anchoring effect in marketing, refers to participants' willingness
 1219 to allocate votes, which can be influenced by an arbitrary value. However, the ordinal utility remains intact among the
 1220 set of preferences.

1223 *7.4.3 Navigating Between Budget, Votes, and Actual Impact.* The third challenge is participants' confusion between
 1224 budget, votes, and outcomes, despite understanding their definitions. One participant stated:

1226 *[...] get rid of the upvote column or just get rid of the word upvote and just really focus on the money column. Listen. You're an*
 1227 *organization or your participant. You have X amount of dollars you need to. You can only distribute X amount of dollars to these*
 1228 *causes. So you have to figure out which ones get the most, which ones don't get as much. [...]*

1229 Interviewer: [...] Do you feel that the more votes you're giving to a cause you're actually spending more on it?

1230 Yeah.

S003 (ST)

1232 Participants like S003 bypassed the quadratic formulation, directly translating votes to resource allocation. While this
 1233 does not invalidate the power of the quadratic mechanism, it causes frustration and friction for participants to construct
 1234 a clear picture of how to make voting decisions. Future interfaces should better communicate these relationships to
 1235 facilitate respondents' trade-offs.

1237 **In summary**, while the interface supports budget management through automated cost calculation, participants still
 1238 face cognitive load from managing the budget. The cold-start problem and the confusion between budget, votes, and
 1239 actual impact are open questions for future research. These challenges highlight the need for better budget management
 1240 support to complete the QS interface.

1243 7.5 Quadratic Survey Usage, Design Recommendations and Future Work

1244 With a deeper understanding of how survey respondents interact with QS and the sources of cognitive load, we
 1245 recognize that while this current interface may not significantly reduce cognitive load, it represents a crucial step
 1246 toward constructing better interfaces to support individuals responding to QS. In this subsection, we outline usage

1249 and design recommendations applicable to all applications using the quadratic mechanism and highlight directions for
1250 future work.
1251

1252 **7.5.1 Usage Recommendation: QS for Critical Evaluations.** Our study highlighted the complex cognitive challenges
1253 and in-depth consideration required when ranking and rating options using QS, even in a short survey. Similar to
1254 survey respondents needing to make trade-offs across options, researchers and agencies seeking additional insights and
1255 alignment with respondent preferences must ensure that survey respondents have the cognitive capacity to complete
1256 such surveys rigorously. QS should be designed for critical evaluations, such as investment decisions, or situations
1257 where participants have ample time to think and process the survey. For instance, revealing the options ahead of time
1258 can aid in preference construction.
1259

1260 **7.5.2 Design Recommendations.**
1261

1262 **Use Organization Phases for Quadratic Mechanism Applications.** Our study demonstrated that preference construc-
1263 tion can shift from operational to strategic and higher-level causes. An additional organizational phase with direct
1264 manipulation capability allows survey respondents to engage in higher-level critical thinking. We believe this approach
1265 should extend beyond QS to other ranking-based surveying tools, such as rank-choice voting and constant sum surveys.
1266 Further research should examine how implementing such functionality alters survey respondents' mental models.
1267

1268 **Facilitate Differentiation through Categorization, Not Ranking.** Participants in our study were less inclined to provide
1269 a full rank unless necessary. The final 'rank' of option preferences often emerged as a byproduct of their vote allocation,
1270 constructed in situ. Therefore, for survey designs to be effective in constructing preferences, it is more important to
1271 facilitate differentiation than to focus on direct manipulation solely for fine-tuning. Emphasizing categorization can
1272 better support participants in articulating their preferences.
1273

1274 **7.5.3 Future Work: Support for Absolute Credit Decision.** Deciding the absolute amount of credits in QS is highly
1275 demanding. Designing interfaces and interactions that address the cold start challenge and help participants decide the
1276 absolute vote value while considering ways to limit direct influences remains an open question. Future research should
1277 explore innovative solutions to support participants in making these complex decisions effectively.
1278

1279 By implementing these recommendations and pursuing future research directions, we can improve the usability and
1280 effectiveness of QS and other quadratic mechanism-powered applications, ultimately aiding respondents in making
1281 more informed and accurate decisions.
1282

1283 **8 Limitations**
1284

1285 Evaluating the QS interface is challenging due to its novelty. During the study, we identified several limitations that
1286 require further research.
1287

1288 **Understanding results influence on decision-makers.** Further research is required to understand how the QS interface
1289 impacts decision-makers and broader societal resource distributions. Since QS is still in its early stages, we prioritize its
1290 widespread adoption and usage before attempting a comprehensive assessment of its influence on decision-making.
1291 Future studies will examine how decision-makers interpret and use QS data, as well as its broader implications for
1292 societal decisions.
1293

Individual differences in cognitive capacity. Variations in individual cognitive capacity influenced participants' cognitive scores. For example, participants with more experience in decision-making might be able to manage multiple options more effectively. A within-subject study could clarify cognitive load shifts, but deconstructing established preferences and altering options further complicates this. Thus, we opted for this in-depth, between-subject study, although the small sample size may introduce noise that distorts the actual cognitive load. Future research should quantify the impact of different QS interfaces. In addition, participants completed this study in a controlled lab environment with options displayed on a large screen. Future work should also explore how individuals respond to QS on smaller devices in a less controlled environment.

Limited experience with QS. Participants had no prior experience with the QS interface. Following a tutorial and quiz, participants proceeded to complete tasks using the QS interface. While participants understood the QS mechanics, familiarity with the interface still influences strategies and cognitive load. As quadratic mechanisms become more prevalent, future research can compare novices and experts.

Duration between clicks to represent decision-making. Click duration may include time spent considering other options, so it must be treated as an approximate measure of decision-making time. For instance, deciding between two options may take longer for the first option and less time for the second. Despite its limitations, this approach provides valuable insights into decision-making within our experimental constraints.

9 Conclusion

In this study, we designed and evaluated a novel two-phase "Organize-then-Vote" interface aimed at guiding Quadratic Survey (QS) respondents in effectively constructing their preferences. Through an in-lab study employing NASA-TLX and interviews, we explored how this two-phase interface influenced individuals' cognitive load and survey response behaviors when engaging with societal issues of varying lengths. The interface's organization and voting phases, designed to reduce cognitive overload by structuring the decision-making process, allowed respondents to differentiate between options before voting. Results revealed that the two-phase design decreased reliance on satisficing behaviors and encouraged more iterative and reflective preference construction, even though it did not clearly reduce overall cognitive load. Nonetheless, this design shift promoted deeper engagement and strategic thinking compared to the text-based interface, especially in longer surveys, by distributing cognitive effort more effectively. Quantitative results confirmed that participants, particularly those responding to the longer survey, exhibited more frequent fine-tuning of their votes, reflecting the iterative nature fostered by the interface. By integrating the organization and drag-and-drop functions, the interface facilitated both preference differentiation and consolidation, making it easier for respondents to refine their decisions. This two-phase interface design supports the development of future software tools that facilitate preference construction and promote the broader adoption of Quadratic Surveys. Future research should explore how to better support individuals in deciding the allocation of budget and design interfaces for smaller devices.

A Voting Interface Breakdown

Compared to digital survey interfaces, there exists a rich literature on voting interfaces, which we argue is a special type of survey interface. We categorize these related works into three main categories detailed below:

1530 *Designs that shifted voter decisions*: For example, states without straight-party ticket voting (where voters can select
 1531 all candidates from one party through a single choice) exhibited higher rates of split-ticket voting [13]. Another example
 1532 from the Australian ballot showing incumbency advantages is where candidates are listed by the office they are running
 1533 for, with no party labels or boxes.

1535 *Designs that influenced errors*: Butterfly ballots increased voter errors because voters could not correctly identify the
 1536 punch hole on the ballot. Splitting contestants across columns increases the chance for voters to overvote [48]. On
 1537 the other hand, Everett et al. [49] showed the use of incorporating physical voting behaviors, like lever voting, into
 1538 graphical user interfaces.

1541 *Designs that incorporated technologies*: Other projects like the Caltech-MIT Voting Technology Project have sparked
 1542 research to address accessibility challenges, resulting in innovations like EZ Ballot [50], Anywhere Ballot [51], and
 1543 Prime III [52]. In addition, Gilbert et al. [53] investigated optimal touchpoints on voting interfaces, and Conrad et al.
 1544 [54] examined zoomable voting interfaces.

B Interface design process

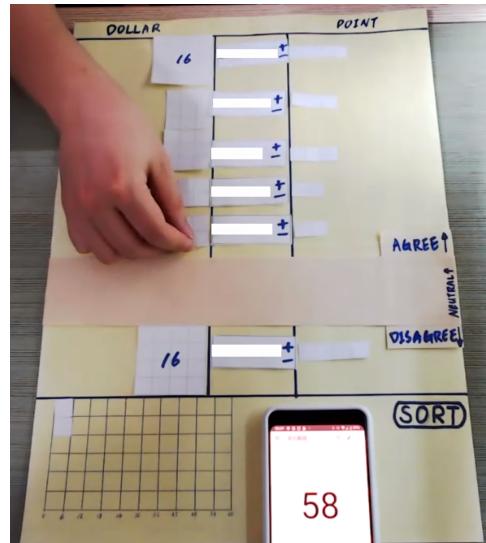

1547 In this section, we outline the design process leading to our final interface. As mentioned in the paper, our design
 1548 iteration began from existing QV applications in the wild.

B.1 Prototype 1: Ranking-Vote

1555 Considering that relative preference is often through ranking items, we tested whether ranking options before voting
 1556 would help establish an individual’s relative preference in our prototype 1. This prototype allowed respondents to
 1557 reposition options before voting. Pretests revealed that respondents rarely moved the options and questioned the
 1558 necessity of full ranking, as it did not influence their QS submission. Additionally, many were unaware that options
 1559 Manuscript submitted to ACM

(a) In this paper prototype, issues are denoted by different numbers that appear on mouseover. Pretest respondents can move options anywhere in the two sections of the interface, one denoting positive and one negative. The blocks represent the cost for each option, with no indication of the number of current votes. The credits are shown in the yellow box on the left.

(b) This paper prototype separates the positive and negative areas with a 'band' at the center. Undecided options are placed inside this band. The cost and the votes on both sides of the interface are denoted by small blocks. The budget is shown in the yellow box below the interface with a numerical counter.

Fig. 13. Initial paper prototypes designed for QS interface

were draggable until shown. This insight indicates that full ranking is unnecessary for establishing relative preferences. Therefore, we decided to ask respondents to select a subset of options instead of requiring a full rank among all options.

B.2 Prototype 2: Select-then-Vote

Based on feedback from Prototype 1, instead of *allowing* individuals to rank options, Prototype 2 implemented a two-phase process that *intentionally* asks respondents to select options to express opinions before voting. As shown in Figure 15, survey respondents selected their preferred options (Figure 15a), and the interface positioned these options at the top of the list for voting (Figure 15b). We identified several issues during the prototype 2 pretest: many respondents marked most options as 'options they care about,' which undermined the design's purpose. Additionally, the lack of clear distinction between selected and unselected options confused respondents about the necessity of Step 1. Thus, we need a clearer distinction and connection between the two phases to effectively construct relative preferences.

B.3 Prototype 3: Organize-then-Vote

Figure 16 shows the last prototype where we built on the previous takeaway by providing finer-grain groupings and creating a clear connection between option organization and voting position. Specifically, we provided three categories: Lean Positive, Lean Negative, and Lean Neutral. Initially, respondents see all options under the section labeled 'I don't know,' which includes only the option descriptions. We ask respondents to move these options into the categories

What societal issues need more support?

Please express your opinion using this survey mechanism as described above. You have a total of \$324 for the following 9 issues. You do not need to use up all your budget, but you cannot exceed \$324.

If you think that an issue needs more support, you can rate the issue higher. Vice versa, you can rate the issue lower if you think it requires less support.

1	+1 rating	-1 rating	Parks and Recreation (Arts and Culture Services; Health and Safety Services; Wildlife Conservation; Zoos and Aquariums)	Your ratings cost \$9. You rated this option +3
2	+1 rating	-1 rating	Human Services (Children and Family Services; Health Services; Education and Child Services; Food Banks; Food Pantries, and Food Distributors; Multipurpose Human Service Organizations; Homeless Services; Social Services)	Your ratings cost \$16. You rated this option +4
3	+1 rating	-1 rating	Arts Culture, Heritage (Literacy, Historical Monuments and Landmark Preservation; Museums; Performing Arts; Public Broadcasting and Media)	Your ratings cost \$4. You rated this option -2.
4	+1 rating	-1 rating	Education (Early Childhood Programs and Services; Vocational Education Programs and Services; Adult Education Programs and Services; General Education; Education Policy and Reform; Scholarship and Financial Support)	Your ratings cost \$34. You rated this option +6
5	+1 rating	-1 rating	Environment (Environmental Protection and Conservation; Botanical Gardens, Parks and Nature Centers)	Your ratings cost \$4. You rated this option -2.
6	+1 rating	-1 rating	Healthcare (Mental Health Services; Substance Abuse Services; Disorders, and Disabilities; Patient and Family Support; Treatment and Prevention)	Your ratings cost \$4. You rated this option -2.

Summary

You have spent \$73 and you have \$251 remaining

Submit

Fig. 14. A Ranking-Vote Prototype: The goal of this prototype is to test whether ranking options prior to voting help establish an individual's relative preferences and reduce effort when voting. Each option is draggable to position in a specific location amongst the full list of options. Votes can be updated using the buttons to the right of the interface with vote count and costs to the right of the interface. A summary box is placed sticky to the bottom of the screen.

This is a playground designed to help you understand how to use **Quadratic Survey**.

There is a limited budget to purchase the food for dinner party tonight. Your friend is asking for your preference of the type of food to get for the dinner party tonight. Please complete the survey below.

Step 1: What is important to you?

In this step, please elect the options that you care about to the left of the column.

All Options	Options You Care About
American	Italian
Japanese	Chinese
Mexican	

Step 2: Quadratic Voting

BACK TO STEP 1

You will be given a budget of a certain amount of **dollars**. You will use the available money to rate the options. If you think more resources should be allocated to a certain issue, you can rate the option higher using the **+1**. If you believe that less resources should be allocated on a certain issue, you can rate the option lower using the **-1**. If you are neutral on an issue, you can choose to **not rate the option**. You are allowed to rate options privately or publicly.

Based on the intensity of your opinion, you can rate each issue **positively and negatively**. The stronger your opinion is, the higher the rating you put in one option. Note that the cost of the ratings would increase quadratically in other words, rating **+1** will cost **X²** (square of X) dollars. The table shows the cost for ratings of 1 to 10 as an example. You can rate higher than 10 or lower than -10 if the budget allows you to do so.

Rating	1	2	3	4	5	6	7	8	9	10
Cost in dollars against budget	1	4	9	16	25	36	49	64	81	100

You cannot exceed the budget, but you do not have to use up all the budget either. You can see your total budget you have and the amount of dollars you have spent already in the **Summary** section below. The interface will provide real-time calculation of the remaining budget you have, the amount of ratings you have done, and the total spent on each option. This interface also provides a drag-and-drop feature to help you complete the survey.

1	+1 rating	-1 rating	Chinese Orange chicken and rice	Your ratings cost \$4. You rated this option +2
1	+1 rating	-1 rating	Italian Pasta and bread	Your ratings cost \$9. You rated this option -3.
1	+1 rating	-1 rating	American Burgers, fries and ribs	Your ratings cost \$0. You rated this option 0
1	+1 rating	-1 rating	Japanese Sushi and udon	Your ratings cost \$0. You rated this option 0
1	+1 rating	-1 rating	Mexican Tacos and burritos	Your ratings cost \$0. You rated this option 0

Summary

You have spent \$13 and you have \$37 remaining

Submit

(a) Options are dragged and dropped to the 'Option You Care About' box.
(b) The previous step collapses showing all voting options.

Fig. 15. A Select-then-Vote Prototype: The goal of this prototype is to nudge participants to focus on a subset of options to vote, rather than ranking all of them. This prototype introduces a two-step voting process. As shown in Fig. 15a, the first step involves selecting options for further consideration. Important options are placed at the top of the list for voting shown in Fig. 15b, but options can be placed anywhere on the list if desired. The rest of the controls remain the same as the previous prototype.

below. Voting controls and information appear on each option once respondents move to the subsequent page, forming a clear connection between option groups, positions, and voting controls.

Feedback indicated that survey respondents are comfortable with the two-phase organize-then-vote design, demonstrating it as a central strategy for our interface development. However, several areas for enhancement were identified:

1665

1666 What societal issues need more support?

1667 Please express your opinion using this survey mechanism as described above. You have a total of \$324 for the following 9 issues. You do not need to use up all your budget, but you cannot exceed \$324.

1668 If you think that an issue needs more support, you can rate the issue higher. Vice versa, you can rate the issue lower if you think it requires less support.

1669 **I don't know:**

1670 Pets and Animals (Animal Rights, Welfare, and Services; Wildlife Conservation, Zoos and Aquariums)

1671 Arts, Culture, Humanities (Libraries, Historical Societies and Landmark Preservation, Museums, Performing Arts, Public Broadcasting, and Media)

1672 Health (Healthcare, Disorders, and Diseases; Patient and Family Support; Treatment and Prevention Services; Medical Research)

1673 Religious Activities (Religious Activities; Religious Media and Broadcasting)

1674 Veterans (Wounded Troops Services, Military Social Services, Military Family Support)

1675 Education (Early Childhood Programs and Services; Youth Education Programs and Services; Adult Education Programs and Services; Special Education; Education Policy and Reform; Scholarship and Financial Support)

1676 Negative

1677 Environment (Environmental Protection and Conservation; Botanical Gardens, Parks and Nature Centers)

1678 International (Development and Relief Services; International Peace, Security, and Affairs; Humanitarian Relief Supplies)

1679 Human Services (Child and Family Services; Youth Development, Shelter, and Crisis Services; Food Banks, Food Pantries, and Food Distribution; Multipurpose Human Service Organizations; Homeless Services; Social Services)

(a) The Organization Interface: Options are shown initially in the first bin labeled as 'I don't know.' Survey respondents can then drag and drop these options into the latter bins: Lean Positive, Lean Neutral, or Lean Negative. Only the details of each option are shown on this interface.

Fig. 16. Organize-then-Vote Prototype: The goal of this prototype is to encourage participants to derive finer grain categories among options before voting. Survey respondents first organize their thoughts into categories and then vote on the options.

First, the dragging and dropping mechanism in the organization phase is cumbersome and may inadvertently suggest a ranking process, contrary to our intentions. Second, placing unorganized options at the top of the voting list is counterintuitive. Third, the voting controls are disconnected from the option summaries, dividing attention between the left and right sides of the screen. These insights guided refinements in the final two-phase interface, adhering to the two-phase organize-then-vote design framework.

C List of Options

We provide the full list of options presented on the survey.

- **Animal Rights, Welfare, and Services:** Protect animals from cruelty, exploitation and other abuses, provide veterinary services and train guide dogs.
- **Wildlife Conservation:** Protect wildlife habitats, including fish, wildlife, and bird refuges and sanctuaries.
- **Zoos and Aquariums:** Support and invest in zoos, aquariums and zoological societies in communities throughout the country.
- **Libraries, Historical Societies and Landmark Preservation:** Support and invest public and specialized libraries, historical societies, historical preservation programs, and historical estates.
- **Museums:** Support and invest in maintaining collections and provide training to practitioners in traditional arts, science, technology, and natural history.

- **Performing Arts:** Support symphonies, orchestras, and other musical groups; ballets and operas; theater groups; arts festivals; and performance halls and cultural centers.
- **Public Broadcasting and Media:** Support public television and radio stations and networks, as well as providing other independent media and communications services to the public.
- **Community Foundations:** Promote giving by managing long-term donor-advised charitable funds for individual givers and distributing those funds to community-based charities over time.
- **Housing and Neighborhood Development:** Lead and finance development projects that invest in and improve communities by providing utility assistance, small business support programs, and other revitalization projects.
- **Jewish Federations:** Focus on a specific geographic region and primarily support Jewish-oriented programs, organizations and activities through grantmaking efforts
- **United Ways:** Identify and resolve community issues through partnerships with schools, government agencies, businesses, and others, with a focus on education, income and health.
- **Adult Education Programs and Services:** Provide opportunities for adults to expand their knowledge in a particular field or discipline, learn English as a second language, or complete their high school education.
- **Early Childhood Programs and Services:** Provide foundation-level learning and literacy for children prior to entering the formal school setting.
- **Education Policy and Reform:** Promote and provide research, policy, and reform of the management of educational institutions, educational systems, and education policy.
- **Scholarship and Financial Support:** Support and enable students to obtain the financial assistance they require to meet their educational and living expenses while in school.
- **Special Education:** Provide services, including placement, programming, instruction, and support for gifted children and youth or those with disabilities requiring modified curricula, teaching methods, or materials.
- **Youth Education Programs and Services:** Provide programming, classroom instruction, and support for school-aged students in various disciplines such as art education, STEM, outward bound learning experiences, and other programs that enhance formal education.
- **Botanical Gardens, Parks, and Nature Centers:** Promote preservation and appreciation of the environment, as well as leading anti-litter, tree planting and other environmental beautification campaigns.
- **Environmental Protection and Conservation:** Develop strategies to combat pollution, promote conservation and sustainable management of land, water, and energy resources, protect land, and improve the efficiency of energy and waste material usage.
- **Diseases, Disorders, and Disciplines:** Seek cures for diseases and disorders or promote specific medical disciplines by providing direct services, advocating for public support and understanding, and supporting targeted medical research.
- **Medical Research:** Devote and invest in efforts on researching causes and cures of disease and developing new treatments.
- **Patient and Family Support:** Support programs and services for family members and patients that are diagnosed with a serious illness, including wish granting programs, camping programs, housing or travel assistance.
- **Treatment and Prevention Services:** Provide direct medical services and educate the public on ways to prevent diseases and reduce health risks.

- 1769 • **Advocacy and Education:** Support social justice through legal advocacy, social action, and supporting laws
1770 and measures that promote reform and protect civil rights, including election reform and tolerance among
1771 diverse groups.
- 1772 • **Development and Relief Services:** Provide medical care and other human services as well as economic,
1773 educational, and agricultural development services to people around the world.
- 1774 • **Humanitarian Relief Supplies:** Specialize in collecting donated medical, food, agriculture, and other supplies
1775 and distributing them overseas to those in need.
- 1776 • **International Peace, Security, and Affairs:** Promote peace and security, cultural and student exchange
1777 programs, improve relations between particular countries, provide foreign policy research and advocacy, and
1778 United Nations-related organizations.
- 1779 • **Religious Activities:** Support and promote various faiths.
- 1780 • **Religious Media and Broadcasting:** Support organizations of all faiths that produce and distribute religious
1781 programming, literature, and other communications.
- 1782 • **Non-Medical Science & Technology Research:** Support research and services in a variety of scientific
1783 disciplines, advancing knowledge and understanding of areas such as energy efficiency, environmental and
1784 trade policies, and agricultural sustainability.
- 1785 • **Social and Public Policy Research:** Support economic and social issues impacting our country today, educate
1786 the public, and influence policy regarding healthcare, employment rights, taxation, and other civic ventures.

1793 D Detailed Qualitative Cognitive Load Breakdown

1794 In addition to the discussion on cognitive load sources presented in the main text, we provide additional details on the
1795 six cognitive dimensions. Among all dimensions, we also provide the codes representing different types of demand in a
1796 table form. The shaded cells represent the percentage of participants citing each source of mental demand, allowing
1797 for comparison within columns. The abbreviations in the columns: ST (Short Text Interface), SP (Short Two-phase
1798 Interface), LT (Long Text Interface), and LP (Long Two-phase Interface). Short and Long refer to the sum across both
1799 interfaces; Text and Inter refer to the sum across both survey lengths. We include Sparklines for comparisons across
1800 these experiment groups.

1805 E Sources of Mental Demand

1806 Table E lists all the mental demand codes.

1809 E.1 Sources of Physical Demand

1811 Physical demand refers to the physical effort required to complete a task, such as physical exertion or movement.
1812 Most participants reported minimal physical demand ($N = 32$), reflected in the low NASA-TLX physical demand
1813 scores (Figure 17). Notably, 11 out of 20 participants who used the two-phase interface mentioned physical demand
1814 from using the mouse, reflecting their increased interaction with the interface. This is further supported by the raw
1815 NASA-TLX physical demand scores (Figure 17), which show a significant visual difference between short and long
1816 two-phase interfaces as well as between text and two-phase interfaces in long surveys. Table 2 presents all the relevant
1817 codes across experiment groups.

Table 1. This table lists all the causes participants mentioned as contributing to their Mental Demand.

[Mental Demand]	Total	Version				Experiment Conditions			
		ST	SI	LT	LI	Short	Long	Text	Inter
Budget Management	14	3	3	5	3	6	8	8	6
Budget within limited credit	5	2	2	1	0	4	1	3	2
Track remaining credits	10	2	2	3	3	4	6	5	5
Maximize credit usage	8	2	3	2	1	5	3	4	4
Operational	12	3	2	4	3	5	7	7	5
Strategic	7	2	4	1	0	6	1	3	4
Preference Construction	39	10	9	10	10	19	20	20	19
Determining relative preference	16	4	4	5	3	8	8	9	7
Option prioritization	17	6	4	3	4	10	7	9	8
Precise resource allocation	30	9	6	9	6	15	15	18	12
Narrow - Consider a few options/personal causes	23	6	6	8	3	12	11	14	9
Broad - Considering all options or higher order values	23	5	5	4	9	10	13	9	14
Demand from Experiment Setup	24	6	6	6	6	12	12	12	12
Many options on the survey	6	0	0	3	3	0	6	3	3
QS Mechanism	4	2	0	2	0	2	2	4	0
Recalling experience or understanding options	20	5	6	4	5	11	9	9	11
Justification or Reflection on response	8	2	2	1	3	4	4	3	5
External Factors	12	3	1	4	4	4	8	7	5
Demand due to Interface	8	2	2	0	4	4	4	2	6
Increase	4	1	1	0	2	2	2	1	3
Decrease	4	1	1	0	2	2	2	1	3

Table 2. Physical Demand Causes: Most participants expressed little or no physical demand. Results reflected that participants in the long two-phase interface required more actions, hence the higher mention of mouse usage as a source.

[Physical]	Total	Version				Experiment Conditions			
		ST	SI	LT	LI	Short	Long	Text	Inter
Reading	4	0	2	1	1	2	2	1	3
Mouse	16	3	5	2	6	8	8	5	11
Vertical Screen	4	1	0	1	2	1	3	2	2
None/Little	32	8	9	8	7	17	15	16	16

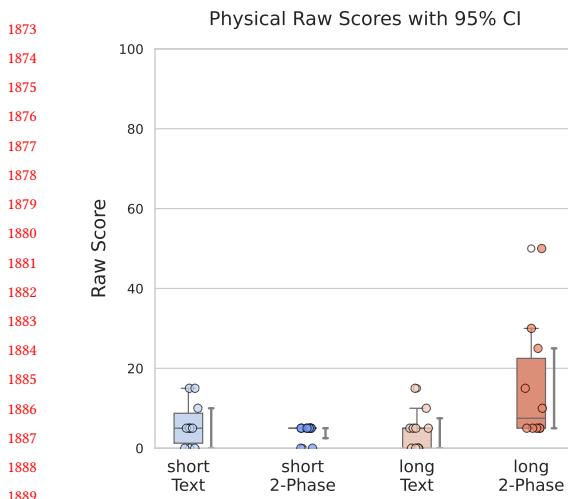

Fig. 17. Physical Demand Raw Score: Participants other than the long two-phase interface reported minimal physical demand. The long two-phase interface had the highest physical demand, likely due to increased mouse clicks and extended time spent looking at the vertical screen.

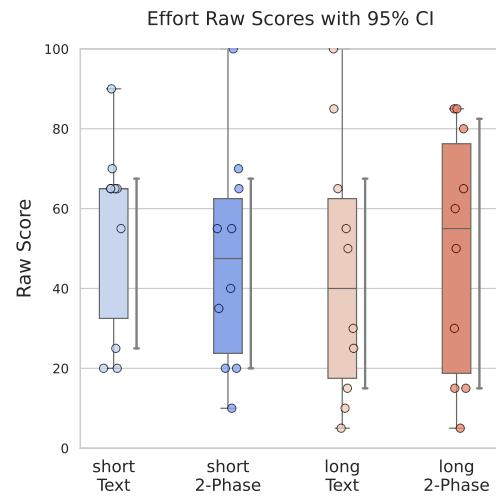

Fig. 18. Effort Raw Score: Effort scores shows indifference across groups.

Table 3. Effort Sources: Participants using the text interface focused more on operational tasks, while those using the two-phase interface focused more on strategic planning.

[Effort]	Total	Version				Experiment Conditions				
		ST	SI	LT	LI	Short	Long	Text	Inter	
Operational	21	6	5	8	2	11	10	14	7	1
Strategic	28	6	8	5	9	14	14	11	17	2
Personal	22	4	7	5	6	11	11	9	13	1
Global	11	2	3	2	4	5	6	4	7	1
None/Little/a bit	9	2	1	3	3	3	6	5	4	1

E.2 Source of Effort

Effort refers to how hard participants felt they worked to achieve the level of performance they did. Since effort includes both mental and physical resource intensity, refer to Section 5.2 and Appendix E.1 for definitions. Raw NASA-TLX effort scores (Figure 18) showed a similar spread across experiment groups, the qualitative analysis showed more distinction that participants using the two-phase interface considered options more comprehensively and felt less effort on completing operational tasks, similar to what we found on mental demands (Section 5.2). Table 3 contains codes.

E.2.1 Effort Source #1: Operational Tasks. 14 of the 20 participants using the text interface mentioned Operational Tasks as effort sources, compared to 7 using the two-phase interface, with the lowest mention by the long two-phase interface group ($N = 2$). Quotes below illustrated participants putting in effort to manipulate the interface.

1925 I wanted to bump up (an option) maybe to 4 or <option> to 5 and realize I couldn't. [...] that would be effort came in of how do I want
 1926 to really rearrange this to make it (the budget spending) maximize?

1927 – S029, short text interface

1928 So it was like it was very ... I have to put a lot of effort in terms of you know ... think about each dimension that if I give one credit to
 1929 <option name> whether it will affect my credits on <another option name>.

1930 – S005, long text interface

1931
 1932 **E.2.2 Effort Source #2: Strategic Planning.** Different from Operational Tasks, 11 participants in the text interface
 1933 compared to 17 participants described strategic planning as sources of effort, with almost all participants ($N = 9$) from
 1934 the long two-phase interface. We further categorize strategic planning into *narrow* and *broad* scopes as we did for
 1935 mental demand section 5.2. Participants using the two-phase interface ($N = 7$) had nearly mentioned double ($N = 4$)
 1936 times regarding global strategies. For example:

1937 And really the bulk of the effort was how to rank order these (options) and allocate the resources behind the upvotes so that I can
 1938 accurately depict what I want ... say, a committee to focus on and allocate actual fungible resources, too. – S019, long two-phase
 1939 interface

1940 Table 4. Performance Causes: Most causes are shared across experiment conditions. We provided qualitative interpretations of their
 1941 own performance assessments.

1942

1943 [Performance]	Total	Version				Experiment Conditions			
		ST	SI	LT	LI	Short	Long	Text	Inter
1944 Operational Action	13	2	3	3	5	5	8	5	8
Budget Control	6	1	1	2	2	2	4	3	3
Preference Reflection	6	1	1	2	2	2	4	3	3
Limited Resources	5	1	2	1	1	3	2	2	3
1945 Social Responsibility	8	2	2	2	2	4	4	4	4
Decision maker	7	1	2	2	2	3	4	3	4
Outcome Uncertainty	7	1	2	2	2	3	4	3	4
1946 Performance Assessment									
Did their best	8	2	1	3	2	3	5	5	3
Feel Good	17	3	5	3	6	8	9	6	11
Good Enough	10	2	2	3	3	4	6	5	5

E.3 Source from Performance

1969 Performance refers to a person's perception of their success in completing a task. Lower values mean good perceived
 1970 performance; higher values mean poor perceived performance. We found minimal qualitative differences between
 1971 experiment groups regarding factors influencing perceived performance. Two influencing factors emerged: *Operational*
 1972 *Actions* and *Social Responsibility*. Despite most participants reporting positively on their performance, nuances exist in
 1973 how different groups interpret their performance.

1974

1975

1976

Manuscript submitted to ACM

1977 **E.3.1 Operational Actions.** Operational actions, like the theme
 1978 presented in temporal demand, refer to specific, executable pro-
 1979 cedures participants perform in the survey. This could involve:
 1980 pressure to spend all credits or stay within budget ($N = 6$), fears
 1981 that final vote choices did not reflect true preferences ($N = 5$),
 1982 or concerns that they had finished the task inefficiently ($N = 6$).
 1983

1984
 1985 **E.3.2 Social Responsibility.** Social responsibility-based con-
 1986 cerns around performance came up when participants reflected
 1987 on how their final vote counts would be perceived by others (S041 *I don't want people to think that I just like don't care*
 1988 about <ethnicity> people at all) or influence real-world decision-
 1989 making (S027 *Some of these things might ... have outcomes*
 1990 *that I didn't foresee*).

1991 All groups cited social responsibility as source to evaluate
 1992 effort. Raw NASA-TLX scores (Figure 19) show participants
 1993 had indistinguishable performance scores. This aligns with the
 1994 interview results where most participants felt positive about
 1995 their final submission.

1996 To dig deeper, we also analyzed participants' language when they described their performance. Expressions like
 1997 "good enough" may be indicative of satisficing behaviors – our results suggest participants are satisfied at similar rates
 1998 regardless of the interface. 1/4 of the participants in the text interface expressed "done their best," referring to exhausting
 1999 their effort. Participants who used a two-phase interface were generally more positive about their final outcome – they
 2000 were twice as likely to report "feeling good" about their final results ($N = 11$ v.s. $N = 6$).

2001 E.4 Temporal Demand

2002 Table E.4 lists all the mental demand codes.

2003 Table 5. Temporal Demand Sources: Decision-making and Operational Tasks are the main causes. Participants framed their decision-
 2004 making sources differently.

2005 [Temporal]	2006 Total	2007 Version				2008 Experiment Conditions			
		2009 ST	2010 SI	2011 LT	2012 LI	2013 Short	2014 Long	2015 Text	2016 Inter

Adhering to the Quadratic Mechanism	5	2	1	1	1	3	2	3	2
Deciding number of votes for an option	4	2	0	0	2	2	2	2	2
Making multiple decisions	3	2	0	0	1	2	1	2	1
Understanding Option	4	0	3	0	1	3	1	0	4
None/Little	16	4	5	5	2	9	7	9	7

2081 F Additional voting behavior data

2082 The reason why we decided to focus on the percentage of remaining credits comes from prior literature ‘scarcity
 2083 frames value’ [95], a driver that makes researchers believe makes quadratic voting more accurate [4]. We did not follow
 2084 Quarfoot et al. [6] in counting accumulated votes over time due to varying total times across individuals.
 2085

2086 In this section, we complement the main text, showing a few additional figures. Figure 20 follows the main text,
 2087 showing all the voting actions over the remaining credit for the four experiment conditions. Here we see two distinct
 2088 patterns between the short survey and the long survey in terms of participant behaviors. In long surveys, participants
 2089 exhibited more actions both when the budget was abundant and when it began to run out. This pattern was more
 2090 pronounced with the long two-phase interface. This difference is why we further focused on the long QS group.
 2091

2116 Fig. 20. This plot counts the number of voting actions when there are x percentages of credits remaining. A KDE plot is provided to
 2117 help better understand the action distribution.
 2118

2119 In addition to the small adjustment plots presented in Figure 12b, Figure 21 presents the comparison between when
 2120 participants make small or large vote adjustments at different budget levels. Revisiting the KDE curve in the second
 2121 row in Figure 20 and the curve of the second row in Figure 21 show a stronger bimodal distribution for small vote
 2122 adjustments across interfaces. In fact, the bimodal distribution is more pronounced in the two-phase interface. This
 2123 suggests that participants make small adjustments both at the beginning and toward the end of the QS. However, the
 2124 two-phase interface shows more frequent and faster edits towards the end. In comparison, participants also made more
 2125 large vote adjustments early on that spread more equally compared to the text interface. This indicates that participants
 2126 had a clearer idea of how to distribute their credits across the options.
 2127
 2128
